It may seem a far step between the route of absorption of particulate substances and that of crystalloid and colloid solutions, and yet opinion is still divided as to how far absorption of the latter solution is primarily along lymphatic or blood vascular channels. In concurrence with the views of Starling and Tubby (1894), Heidenhain (Orlow, 1895) and Mendel (1898), Dandy and Rowntree[12] in 1914 concluded that absorption of fluids was primarily into the blood and not into the lymphatics. They studied the absorption of fluids (isotonic salt solution containing phenolsulphonphthalein) from the normal peritoneal and pleural cavities in dogs, and conclude that there is a very active absorption of fluids from all parts of the normal peritoneal and pleural cavities, which is essentially hemic and not lymphatic. Peritoneal absorption is practically equal in all postures except pelvis down, in which it is 15 per cent less than other postures; likewise, pleural absorption is 13 per cent less in pelvis down than in other postures.

Although not concerned with absorption from the lower respiratory tract but rather with absorption in the body in general, Putnam[13] devised an ingenious experiment, using the peritoneum of rabbits, cats and dogs in the living intact animal, and he repeatedly thus dialyzed flowing blood against indifferent fluids. Dialysates thus obtained varied according to the fluid employed; but, in general, they contained a trace of protein matter and crystalloids occurring naturally in the blood plasma or artificially introduced into the circulation.

Under certain conditions, fluids in the peritoneal cavity can come into an apparently complete osmotic equilibrium with the blood plasma. The speed of diffusion of different molecules varies inversely with their respective sizes. Colloids in general are not transmitted from the blood stream into fluids in the peritoneal cavity. Colloids in solution are, however, absorbed from the peritoneal sac, although not as rapidly as crystalloids. Changes in volume of hypotonic and hypertonic solutions occur in the direction that might be predicted from a consideration of osmotic forces at work, but never to exactly the extent demanded by the theoretical laws of pure osmosis. Absorption into the blood stream is always greater than the expected diffusion from the peritoneal cavity, and sometimes very much greater.

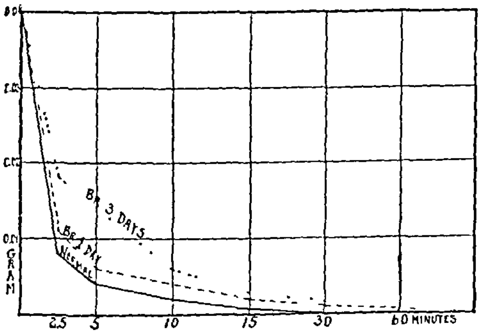

Fig. 2.—Retardation of the absorption of 2 cc. of 2 per cent sodium sulphocyanate solution in the lungs, one and three days after gassing with bromine that resulted in an acute pneumonitis.

It is concluded that while the major part of the transfer of crystalloids to and from the peritoneal cavity may be explained as being due to a simple colloidal membrane, the presence of another pathway, capable of transmitting colloids and particles as well as true solutions, and oriented only away from the peritoneal sac, must be predicated. Whether this second mode of transmission is due to some form of "vital activity" (phagocytosis, potocytosis) or whether it is due to simple mechanical filtration through intercellular spaces, actual or potential, of appropriate size, is still obscure.

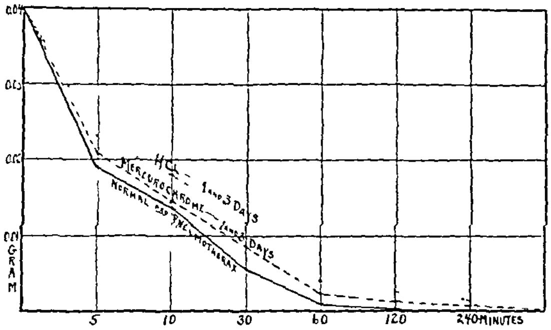

Fig. 3.—Retardation of the absorption of 2 cc. of 2 per cent sodium sulphocyanate solution in acute pleuritis. The inflammatory reaction was greater after 2 cc. of 0.2 per cent hydrochloric acid solution than after 2 cc. of 0.2 per cent mercurochrome solution. In pneumothorax, no retardation was apparent as compared to normal.

The exclusive hemic route of absorption of crystalloids and lymphogenous route of colloids is chosen by two recent investigators. Katsura[14] studied the absorption of aniline dyes in the normal peritoneal and pleural cavities of rabbits and dogs, and concludes that crystalloid dyes are, even in powder form, rapidly resorbed by the blood stream, dependent on the amount introduced. Colloidal dyes are resorbed much less rapidly and by the lymph stream. The lymph vessels of the peritoneum are not exclusively emptied into the thoracic duct but partly into the right lymphatic duct. The lymph paths of the right pleura are not to the right lymphatic duct but, like that of the peritoneum and left pleura, mainly to the thoracic duct. In addition to absorption of crystalloids and colloids under normal conditions in the peritoneum and pleura of dogs, less so in rabbits, guinea-pigs and white rats, Notkin[15] also studied absorption from those serous surfaces under experimental pathologic conditions. He found that crystalloid salt solutions are primarily absorbed by the blood vessels, and believes that the lymph vessels may take some part in this. The absorption in the living animal is dependent on physicochemical factors (diffusion, osmosis, etc.), but vital factors play a part in that these substances act as a foreign substance and cause a reaction which is absent in dead tissues. Hemoglobin injected into the blood stream appeared in the urine in twenty-seven minutes; injected into the serous cavities

(peritoneum or pleura), they appeared in three hours forty-six minutes, and, injected into inflamed (by iodine potassium iodide solution) serous cavities, appeared in eight hours twenty-five minutes. It is concluded that the lymph vessels play an especially important rôle in the economy of the living animal since it is only through these vessels that the tissue fluids, like lymph, transudates and exudates are resorbed.

Aside from the early partially inexact studies by Grober[16] in 1901, from which he maintained that resorption from the pleura occurred by diffusion and osmosis as well as by respiratory movements (pumping system of the intercostal lymph vessels, pressure of the lung against the thoracic wall and the movement of the pleural surfaces against each other), and that resorption from the inflamed pleura is diminished, and a recent review of the literature with inconclusive personal experiments with many substances including various crystalloids, fats and lipoids, proteins, epinephrine, etc., in guinea-pigs by Jedlička[17] in 1924, there is just one other of recent date that is of value in a consideration of the absorption of liquids from the lower respiratory tract. This study was initiated by Winternitz and Smith[18] in the hope of utilizing the intratracheal route for the more direct application of therapeutic agents in pulmonary inflammatory conditions. While the main objective was not attained, it was found that the lungs would tolerate great quantities of fluid without untoward effects, and they were also led to challenge the significance of pulmonary edema as a cause of death. All the experimental work was done on normal dogs, and the material was introduced into the lungs by tracheal insufflation. It was found that 20 cc. per kilogram of body weight (from 200 to 450 cc. total volume) could be introduced into the lungs without evident harmful effect, and 30 cc. per kilogram merely overflowed back through the trachea. The fluid introduced found its way into the alveoli. Absorption from the lung was determined by noting the phenolsulphonphthalein excretion in the urine. After intravenous injection, the urine was positive in five minutes; after intrapulmonary, in thirteen minutes, and after intramuscular, in fifteen minutes. The absorption of 20 cc. of salt solution per kilogram of body weight from the lungs requires a considerable period of time. After eighteen hours much has disappeared, and within four days it has been absorbed without a trace. In the interim, however, and for several hours after insufflation, a degree of artificial edema is encountered which is greater than that when death is ascribed to this condition.

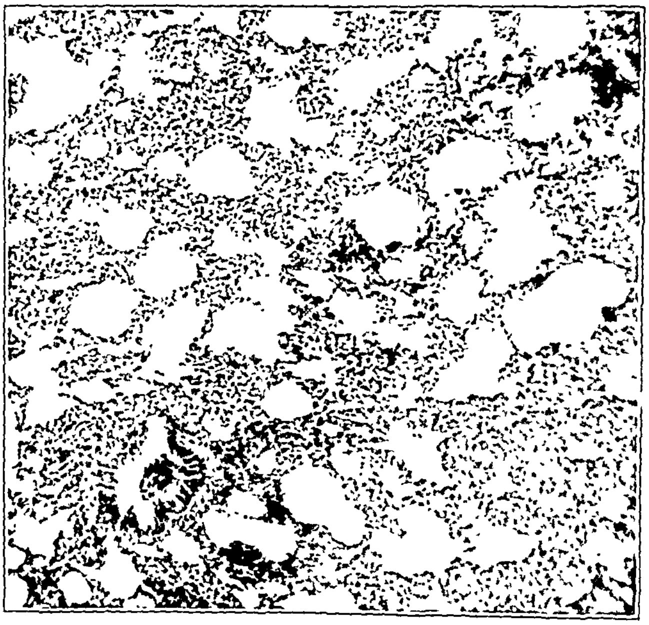

Fig 4.—Pneumonitis three days after bromine gassing resulting in retardation of absorption (compare fig 2)

Although Winternitz and Smith abandoned the possibility of washing out the lungs in acute inflammatory conditions in these organs on account of the danger of dissemination of infection and aggravation of the disease, it seemed advisable to obtain further information on the localization and absorption of liquids from the lower respiratory tract under different conditions so that this information might be further applied as a warning against dangerous procedures or might open the possibility of rational diagnostic or therapeutic methods. Earlier reports from the laboratory of the National Jewish Hospital have been concerned mainly with the pulmonary localization of particles suspended in the inspired air, or with aspirated and injected liquids containing particulate material.[19] The study to be reported below is concerned with the problem of the absorption of liquids from the lungs and pleura under normal and pathologic conditions. This problem has been touched on only saliently or indirectly by previous investigators. Initially it was hoped that aniline dyes might be utilized as an index of absorption, and as a preliminary step a number of crystalloid and colloid dyes, obviously of intense color, were tested by intracutaneous injection into guinea-pigs to determine the concentration tolerated by the tissues without visible injury and the rate of absorption from the local site. Of those tested, brilliant cresyl blue, neutral red, cresyl echt violet, scarlet M 00 and Victoria blue produced local ulcers in concentrations down to 0.5 per cent, while azorubin and rose bengal produced ulcers in 1 per cent and transient tissue changes in 0.5 per cent. Trypan blue and trypan red (both colloidal) produced a transient edema in 2 per cent concentration, but was without effect on the tissues in 1 per cent. The local color with both these dyes persisted as long as the twenty-fifth day, and by intraperitoneal injection 4 cc. of 1 per cent trypan blue colored a guinea-pig blue for twenty days.

Alkali blue produced a transient edema in 2 per cent solution, but was without detrimental effect on the tissues in 1 per cent, and the color persisted locally for more than one month. Vital red produced no appreciable tissue changes in 2 per cent, but its color would not permit satisfactory reading in the body. Indigo carmine and acid fuchsin, both crystalloid dyes, produced no appreciable tissue changes in 2 per cent concentration, rapidly faded within a few hours (to absence within twelve hours) and disappeared from the site of injection. The red color of acid fuchsin made it unserviceable for immediate identification in the body, even though satisfactory otherwise.

These preliminary tests made it obvious that only one dye—indigo carmine—would prove at all satisfactory for absorption tests if color, tissue tolerance and ready absorption were considered of importance. All white guinea-pigs were used, and the appearance of the blue color as determined by the bluing of the skin was used as an index to absorption from the lungs, pleura, peritoneum and subcutaneous tissues after the injection of a constant amount and concentration of the dye (indigo carmine) solution (2 cc., 2 per cent). An inconsistency arose, however, in the fact that the rate of absorption as determined by the appearance of the blue skin color regardless of the site of injection into the subcutaneous tissues was much more rapid than after intratracheal, intrapleural or intraperitoneal injection, although the pulmonary rate exceeded the pleural, and the latter the peritoneal.

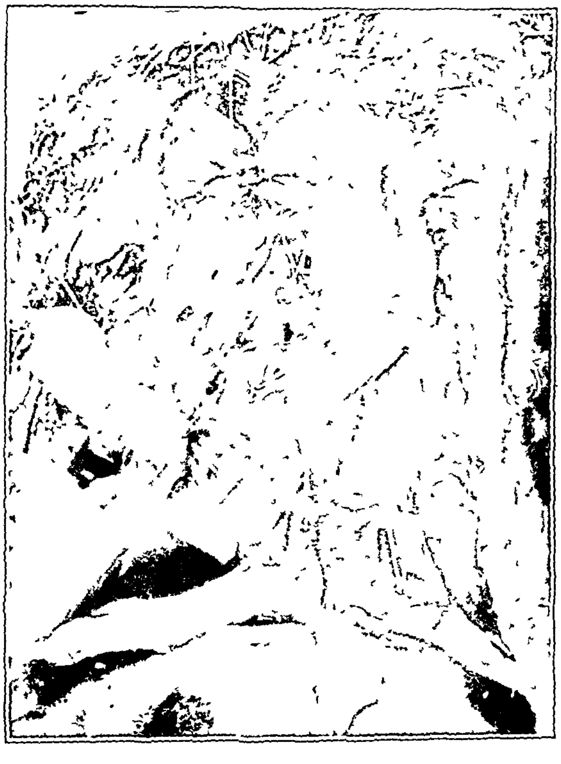

Fig 5.—Fibrinous pleurisy with effusion in pleuritis three days after the intrapleural injection of hydrochloric acid (0.2 per cent) *resulting in retardation of absorption* (compare fig 3)

Attempts to remedy the discrepancies by quantitative determinations of the dye in the blood serum at different intervals also proved insufficiently accurate. It was finally decided that the only accurate method of gaging the rate of absorption from a certain portion of the body would be to examine the site of injection itself and at regular intervals after injection. All attempts to work up a quantitative chemical method for determining the amounts of indigo carmine contained in tissues after injection proved unavailing, and dyes were discarded in preference to sodium sulphocyanate, which in intracutaneous tests proved to be without perceptible injurious effect on tissues in concentration as high as 2 per cent. The method of analysis briefly consisted of grinding the tissues (lung, etc.) in a mortar with sand, adding 30 cc. of 10 per cent trichloracetic acid solution, allowing the mixture to stand until the supernatant liquid is clear, and then filtering. The residue is washed several times and the entire combined filtrates diluted to 200 cc., and to 50 cc. there is added 0.7 cc. of 10 per cent ferric chloride solution and the color is compared with a standard in a colorimeter. In the case of pleural or peritoneal fluids, the spaces are washed out well with 100 cubic centimeters of water, and 30 cc. of 10 per cent trichloracetic acid is added and the procedure is continued as with lung. Since the rate of absorption of any foreign substance or fluid in the body or of extravasated pathologic fluids must be dependent on a number of factors, such as the volume, the concentration and the state and condition of the tissues in which absorption is taking place, it is advisable in experimental studies to unify and control as many of these factors as possible. This was done by using in all the studies reported here 2 cc. of 2 per cent sterile sodium sulphocyanate solution. Since absorption from various parts of the body is to a great extent relative and dependent on numerous variable factors, absorption from the lower respiratory tract was compared with that from the peritoneum and subcutaneous tissues. As previous observers uniformly found absorption not to vary appreciably from different locations and of different substances (crystalloids or colloids) in different species, the guinea-pig was chosen for this study.

The rate of absorption of 2 cc. of 2 per cent sodium sulphocyanate solution from the lungs (after intratracheal injection with the animal in the head-up position), pleura, peritoneum and subcutaneous tissues was determined by analyzing guinea-pigs at various intervals after injection, with the results graphically shown in figure 1.

An examination of figure 1 reveals that the absorption of 2 cc. of 2 per cent sodium sulphocyanate solution from the lungs after intratracheal injection exceeds that from the normal pleural, peritoneum or subcutaneous tissues. How far the absorption from the lungs is responsible for the more rapid rate of absorption from the pleura over that of the peritoneum and subcutaneous tissues was not determined, although this, combined with the motility of the chest, may offer a possible explanation.

In order to determine the effect of acute inflammatory conditions in the lungs and pleura on absorption, a series of guinea-pigs was given injections of 2 cc. of 0.2 per cent hydrochloric acid and 2 cc. of 0.2 per cent mercurochrome-200 soluble [20] into the right pleura, and another series was given inhalations of bromine gas. The intrapleural injections of hydrochloric acid and mercurochrome were determined on in preliminary tests as being capable of producing a decided acute pleuritis without endangering the immediate life of the animal; nine of ten animals thus treated would easily survive for more than two weeks. The bromine exposures were given in a chamber about 2 by 2 by 3 feet in which from six to eight guinea-pigs were placed for hix hours and exposed to the vapors from 0.25 cc. of liquid bromine introduced at hourly intervals. This produced a variable acute pneumonitis from which the animals would gradually recover. An occasional guinea-pig would die shortly after exposure, but the majority of those surviving for one day would show no further general life endangering consequential effects. Bromine inhalations were used in preference to the intratracheal injection of liquids on account of its uniform effect on the lung in distinction to the irregular distribution of the changes occurring after the introduction of irritating liquids. The results of the absorption tests with 2 cc. of 2 per cent sodium sulphocyanate solution one and three days after the intrapleural injection of hydrochloric acid and mercurochrome, and bromine gassing are recorded in figures 2 and 3. For convenience of comparison, the normal curves of absorption for the lung and pleura are included in the charts.

---

[20] Corper, H J.: Pathologic Changes in Lung from Use of Mercurochrome 220 Soluble, J. A. M. A **85**: 256 (July 25) 1925.

An examination of figures 2 and 3 reveals a decided retardation of the absorption of the sodium sulphocyanate in acute inflammatory conditions of the pleura produced by hydrochloric acid and mercurochrome, and of the lungs produced by bromine gassing one and three days prior to the absorption tests.

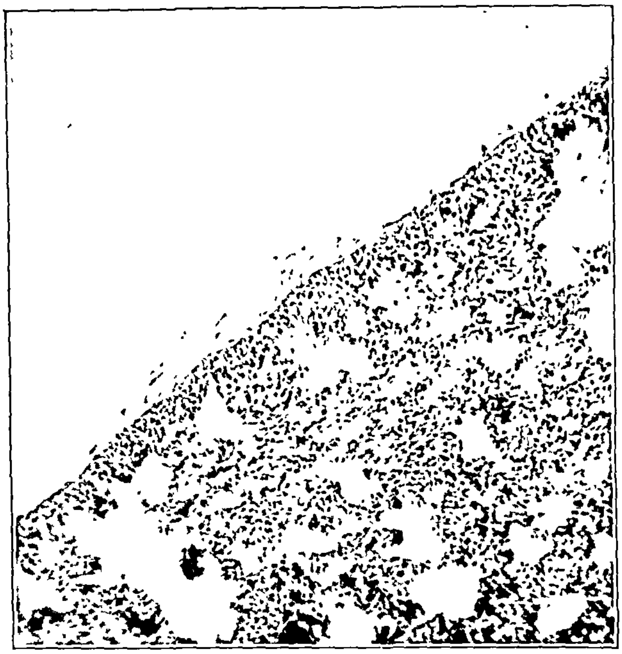

Fig. 6.—Lung with fibrin deposits and pleuritis (same as figure 5).

In order to note just how far this retardation of absorption from the pleura is due to the inflammatory condition itself or due to a separation of the pleural surfaces as a result of the extravasated fluid, the absorption of sodium sulphocyanate was tested shortly (from five to ten minutes) after the institution of artificial pneumothorax by right intrapleural injection of from 15 to 20 cc. of air, which produced a good compresssion. In the guinea-pig, this amount of air produced a bilateral pneumothorax. The pleurisy produced by hydrochloric acid and mercurochrome were also bilateral, so that the studies may be considered to cover the entire pleura of both sides of the chest instead of being monolateral as might be assumed from the injection into the right side of the chest. The graph of absorption of 2 cc. of 2 per cent sodium sulphocyanate solution from the pleura, as illustrated by the time and amount recovered, shows no appreciable change from the absorption noted from the normal pleura. This is illustrated in figure 3, the same absorption curve sufficing for the normal and pneumothorax animals.

It would seem from this study that resorption from the pleura primarily is dependent not on physical changes in the chest, such as occur in artificial pneumothorax, but rather on the grade and amount of inflammatory changes in the pleura. It is to be noted that the retardation of absorption in the hydrochloric acid pleuritis, which was of more severe grade, is greater than that in the mercurochrome pleuritis.[21]

SUMMARY AND CONCLUSIONS

The general problem of the absorption of liquids as applied to the medical sciences is intimately associated with the biology of the body cell, since all fluids and particulate substances passing into or out of the human economy or from one tissue to another do so through the medium of the cell; the existence of stomas as once maintained by von Recklinghausen being now denied. That the laws of osmosis and diffusion play an important part in absorption and resorption of liquids is in accord with present day conceptions, but there are certain unexplained "vital" factors concerned which require further elucidation. That phagocytosis is of primary significance in the absorption and transportation of particulate substances seems well established, but opinions are still divided, and justly so, as to the relative significance of the blood and lymph vascular systems in the absorption of crystalloid and colloidal substances. It seems well at present with the available scientific evidence to consider that both systems play a part in the absorption of both crystalloids and colloids, though the predominant part played in this may depend entirely on the individual circumstances in each case. Probably with most simple molecular crystalloids the main route of absorption is hemic, while with simple colloids it is along lymphatic channels. The difficulty in ascribing to either a specific absorptive function lies in our lack of knowledge of the physicochemical changes wrought in a substance passing through the tissue cells.

Absorption and resorption of liquids from the lower respiratory tract, the lungs and the pleura follow the main principles of absorption in other parts of the human economy, but the anatomic structure and physiologic function lend to these tissues differences that are still to be determined. The rapidity of absorption of crystalloids from the lungs and pleura exceeds that from the peritoneum and subcutaneous tissues. Absorption of crystalloids is more rapid from the lungs than from the pleura, and it is possible that absorption from the lungs in part accounts for the rapidity of absorption from the pleura. The rapidity of absorption of liquids from the lungs is probably to a great extent accounted for by the vascularity and large total surface of the terminal respiratory divisions, the alveoli.

The absorption of crystalloids by the pleura is not influenced by artificial pneumothorax instituted shortly before and resulting in a decided collapse of the lungs. Acute inflammatory conditions affecting the pleura, produced by chemical means (hydrochloric acid and mercurochrome), retard the absorption of crystalloids from the pleura. Acute inflammatory conditions affecting the pulmonary parenchyma, produced by gassing with bromine, retard the absorption of crystalloids from the lung after intratracheal injection. In the application of procedures to the lungs and pleura for diagnostic and therapeutic purposes, these facts must be borne in mind.

THE RESULTS OF DIATHERMY IN PELVIC INFECTIONS *

THOMAS H. CHERRY, M.D.
NEW YORK

The favorable results reported by Corbus, from the use of diathermy in the treatment of gonorrheal urethritis and endocervicitis, encouraged me to investigate its feasibility as a therapeutic agent in intrapelvic infections of the female. If satisfactory results could be obtained in urethritis and endocervicitis, it seemed logical to expect that it might prove equally efficient in adnexal disease of gonorrheal origin.

The principle on which the germicidal influence of diathermy depends in gonococcal infections is the generation of heat in the tissues, sufficient to destroy the vitality of the bacteria. It is a well known fact that the gonococcus dies after an exposure for ten minutes to 42 C., and whatever success diathermy has achieved in the treatment of this type of infection is due to this biologic alteration.

It may be said, by way of explanation, that diathermy is the application to the body of an electrical high frequency current that generates heat in the tissues between two electrodes. The degree of heat is controlled by the size of the electrodes, the amount of current utilized, the duration of the application, and the density of the tissues treated. The greater the density of the tissues traversed by the current, the greater the amount of heat developed. The resistance of tissues varies, according to their density, in the following order: bone, cartilage, ligaments, fascia, skin, muscle and fat. These are important factors when applications of diathermy are made, especially when higher degrees of heat are desired than those used in gonorrheal infections.

The depth of heat penetration can readily be regulated by varying the size of the electrode (fig. 1). When two electrodes of equal size are used, the maximum temperature will be equidistant from them; when electrodes of different sizes are applied, the greatest degree of heat will be near the smaller one. It is therefore possible to localize any degree of heat at any depth by observing these principles. The amount of heat the normal tissues will tolerate before destruction or coagulation occurs probably varies between 55 C. and 58 C. I have applied diathermy through the abdomen of a dog, heating the bladder and rectum to 52 C., without the production of histopathologic changes. I have also applied 55 C. to the human cervix for ten minutes without any gross tissue changes following. We know definitely that tissue is destroyed at 60 C.

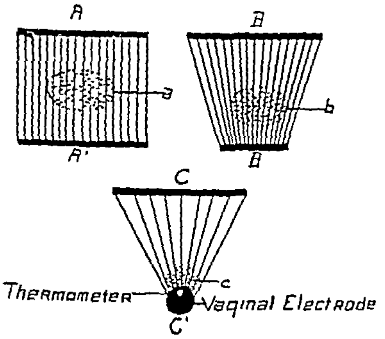

Fig. 1.—Maximum degree of heat with different size electrodes: *AA'*, two electrodes of similar size; *a*, location of maximum degree of heat midway between the two electrodes; *BB'*, electrodes of unequal size; *b*, maximum degree of heat nearer the smaller electrode; *C*, surface electrode; *C'*, vaginal electrode with the thermometer opening; *c*, location of greatest degree of heat.

Medical diathermy is a term applied when the tissues are heated within the boundaries of tissue toleration. Its effect is to produce a hyperemia that quickens the circulation so that the inflamed area treated receives more blood through the dilated capillaries. This brings about a reduction of the stasis in the engorged blood vessels and relief of pain from pressure on the nerve filaments. There also occurs a more rapid absorption of the exudate, for by the increased flow of blood to the pathologic site, a mobilization of the body's natural defenses takes place.

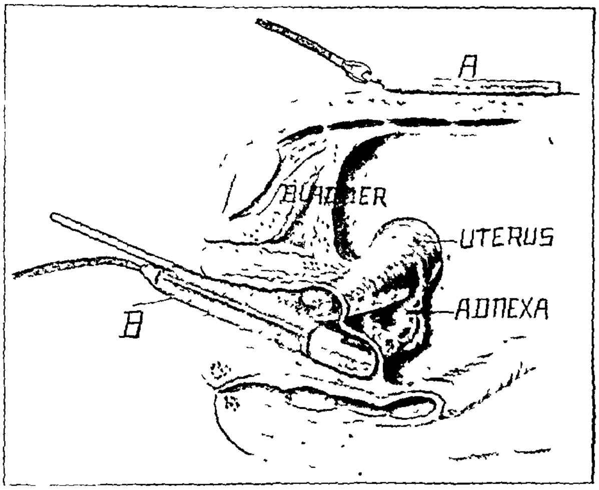

Fig 2.—Abdominovaginal application of electrodes: *A*, abdominal water cooled electrode. *B*, vaginal electrode, with the thermometer inserted, registering the temperature of the vaginal vault. The temperature of the adnexa is from 2 to 3 degrees C. greater than the vaginal temperature

Surgical diathermy, or electrocoagulation, refers to the destruction of tissue by the utilization of degrees of heat above 58 C. This can be attained with any type of electrode, but the employment of one large and one small electrode is the usual method. By means of this therapy new growths or inflamed structures can be destroyed.

In the investigation of the therapeutic application of diathermy to intrapelvic infections, preliminary experimental work on the cadaver was done to ascertain where the maximum degree of heat would register with different types of electrodes.

Since the inflamed adnexa usually prolapse in the culdesac of Douglas, it seemed desirable to ascertain whether the maximum heat units could be concentrated in this area. Without relating the details of the experimental work, I may say that it was found that, with an abdominal electrode measuring 18 by 12.5 cm., and a vaginal electrode (the exposed active surface measuring 5 by 3 cm.), this region was readily heated to 46 C., while the vaginal temperature registered 44 C. A special electrode was made through which a hole was drilled near its surface to hold a thermometer, the bulb being exposed through a small window at the distal end. This allowed the bulb to come in contact with the vaginal vault (fig. 2). Through this contrivance, by adding 2 C. to the temperature registered in the vaginal tissues, the approximate degree of heat in the adnexa was estimated. This can only be approximate, because the amount of heat radiation by the circulating blood cannot be determined.

The question also naturally arose: What effect would prolonged maintenance of heat have on large pyosalpinges or tubo-ovarian abcesses? Electrotherapeutists and authorities on physiotherapy have stated that diathermy should never be used in cavities containing pus, in which no outlet was present for drainage, and have particularly cautioned against its use in the pelvic pathologic processes mentioned. In spite of these opinions, it seemed reasonable to assume that, if the gonococcus was the inciting factor producing such pelvic lesions, and that if a penetration of the diseased structure by heat to 42 C. could be attained, the causal agent would be destroyed, with an incidental reduction of the inflammation. Furthermore, the active hyperemia produced should aid in the rapid absorption of the products of infection and should promote resolution.

---

* From the Gynecological Division, Harlem Hospital.

* Read before the Section of Obstetrics and Gynecology, New York Academy of Medicine, Feb. 2, 1926.

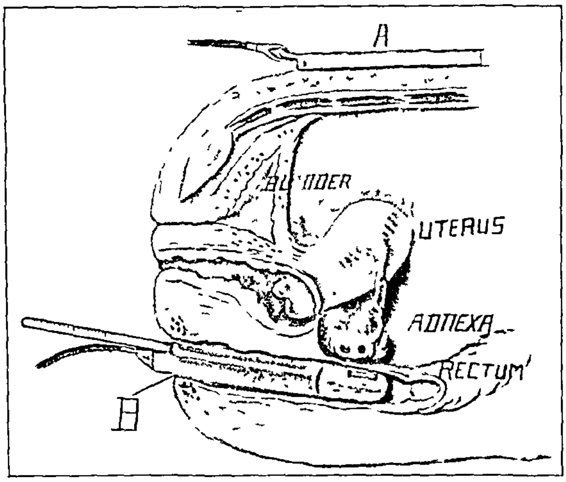

Fig. 3—Abdominorectal application: *A*, abdominal water cooled electrode; *B*, rectal electrode with thermometer This method of application probably is the best for therapeutic purposes, but not so comfortable to the patient

Acting on this assumption, 100 patients with adnexal disease were treated at the Harlem Hospital with diathermy. In all the patients the gonococcus was a causal factor of the disability. This was ascertained by positive urethral or cervical smears in most instances. In others whose smears were negative but contained numerous pus cells, it was assumed to be so, because there was a concomitant subacute or chronic urethritis, endocervicitis, skenitis or bartholinitis. The chief complaint on admission was abdominopelvic pain. This was due to either an initial adnexal infection or an acute exacerbation of a chronic inflammation. All patients had an accompanying endocervicitis; some had urethritis, Skene's duct involvement, or bartholinitis which, in my opinion, classed them as gonorrheal primarily.

The degree of pelvic involvement varied from small, thickened, tender adnexa to large pus tubes or tubo-ovarian abscesses that entirely filled the pelvis. In some instances the masses extended above the pelvic brim.

Table 1.—*Data of Adnexal Disease in One Hundred Patients*

Patients having adnexal disease without masses..........	23
Patients having adnexal disease with masses..............	77
Total number of cases................................	100

There were seventy-seven patients who presented pelvic or abdominopelvic masses; there were twenty-three patients without masses, but whose adnexa were thickened and tender.

Irrespective of the severity of the infection and the degree of pelvic pathologic change, diathermy treatments were instituted as a routine in all cases. The bipolar current was used throughout the entire series. The methods of administration employed were the abdominovaginal, abdominorectal (fig. 3) and abdominosacral application (fig. 4) of electrodes. The abdominovaginal application was made 139 times, while the sacro-abdominal route was utilized sixty-two times. The abdominovaginal application seemed the most practicable. It was attended with less discomfort to the patient than the rectal route; furthermore, it required less time and current than the sacro-abdominal route to produce the desired pelvic temperature.

The abdominovaginal application consisted of an abdominal electrode placed above the pubes, in contact with the skin, and a vaginal electrode, through which a thermometer was inserted, with the exposed surface placed behind the cervix, in contact with the vaginal vault. Sufficient current was utilized to raise the vaginal temperature from 42 to 43 C. (1,500 to 2,500 milliamperes). It was estimated that the maximum temperature in the inflamed adnexa was from 44 to 45 C. The current was then stabilized, and the temperature was maintained from fifteen to thirty minutes. The treatments were repeated at from three to five day intervals. As all these patients had a coexisting endocervicitis, the cervix was also treated, either at the same sitting, or at another time, with diathermy administered by the Corbus thermophore. Patients who had an associated urethritis were treated in a similar manner. These treatments consisted in applying an abdominal surface electrode and inserting the thermophore into the cervix or urethra (figs. 5 and 6). The amount of current utilized varied from 500 to 1,000 milliamperes. In the endocervicitis group, forty-eight patients were treated. Among these, twenty-four were cured or markedly improved, and twenty-four showed no improvement at all. My personal observation is that the application of low degrees of heat (from 42 to 43 C.) to the cervical canal is efficacious only in acute or subacute inflammations of the endocervix, not in the

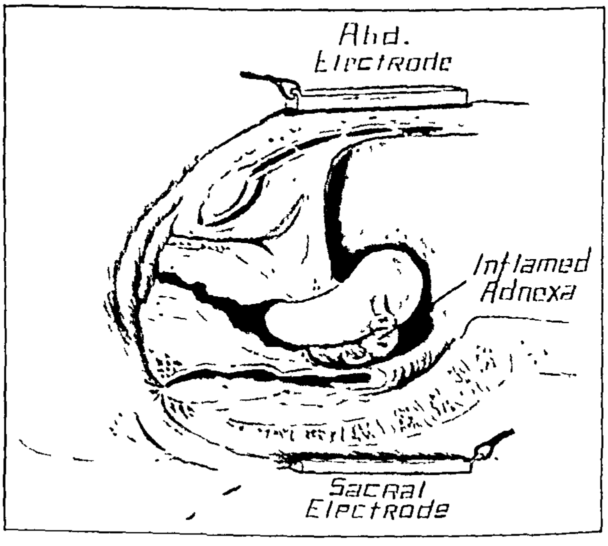

Fig. 4.—Application of abdominosacral electrodes This method requires more current and longer time in order to obtain the desired temperature in the adnexa.

chronic type. In the latter, it is preferable to destroy entirely the infected area by coagulation from the internal to the external os.

In the urethritis group, of thirteen patients treated, six were cured, six improved and one not improved. There were seven patients who received two or more diathermy treatments; of these five were cured, one improved and one not improved. This group, though too few in number for any definite conclusions to be drawn, at least causes one to believe that better results could be obtained by more frequent and longer applications of diathermy, as shown in the small subgroup of seven cases. I consider the clearing up of the lower genital tract infection important to prevent reinfection of the adnexa.

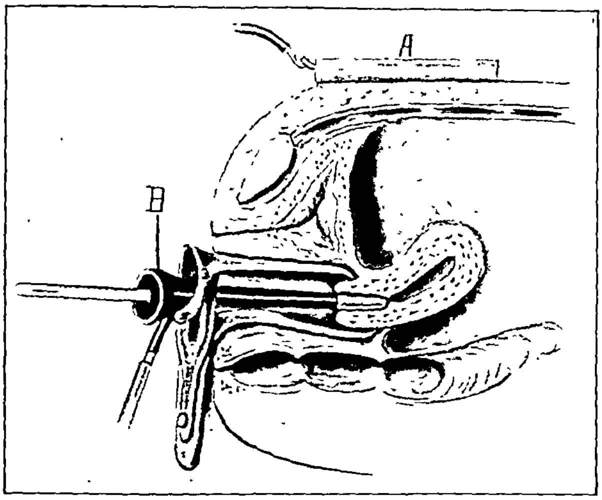

Fig. 5.—Application of diathermy in endocervicitis: *A*, abdominal water-cooled electrode; *B*, Corbus thermophore with thermometer registering the degree of heat in the electrode. The endocervical tissues register from 1 to 2 degrees C. higher than that indicated by the thermometer.

The most striking feature of the diathermy applications was the almost instant relief of pain in all cases. Among the seventy-seven patients who had pelvic masses, there was a disappearance of the masses in eighteen instances, and a reduction in the size of the masses in fourteen, making a total of thirty-two, or 41.5 per cent. The complete disappearance of the pelvic masses seemed more apt to occur in those having an initial attack of adnexal infection. While the tumefaction in chronic infections may be reduced in size, with rapid subsidence of the acute symptoms, the pelvic lesions remain as palpable structures, quiescent and innocuous. Such a result can be attained only by the prolonged use of diathermy. Of the seventy-seven patients having adnexal disease with masses, forty-nine were entirely relieved of symptoms, operation being unnecessary or refused by the patient.

Table 2.—*Data in Treatment of Patients with Adnexal Masses*

Patients with masses operated on	28
Patients with masses entirely relieved of symptoms; operation unnecessary or refused by patient	49
Total	77

On the twenty-eight patients whose adnexal masses persisted, following repeated diathermy applications, abdominal sections were performed. One cannot help but compare the operative findings in these patients with others of a similar nature who did not have preoperative diathermy. The pelvic structures appeared more hyperemic; they were soft, edematous and smooth; the adhesions were vascular and thin, not the thickened fibrous structures usually seen. Consequently, the masses were easily delivered with a minimum of trauma to important structures, and their rapid removal was facilitated. The contents of the masses consisted of a thin, watery, straw colored fluid, instead of the usual thick, creamy, purulent exudate. All cultures taken from the removed adnexa were negative.

The postoperative convalescence of this group was remarkably free from abdominal discomfort, pain, vomiting and distention. No doubt this was due to the lessening of operative trauma by the easy removal of the masses. Two wound infections occurred in the twenty-eight patients operated on, making 7.1 per cent, against 30 per cent wound infections in a large series that had no preoperative diathermy treatment.

I would like to emphasize that the results can be greatly improved in private practice and in institutions when more time can be allotted to each treatment. Many of these patients had only fifteen minute applications, while in private work thirty-five minutes is the minimum duration.

Regarding the uses of diathermy in pelvic infections produced by bacteria other than the gonococcus, my experience has been limited to three instances. In one postpartum case of three weeks' duration, with a pelvic mass of moderate size, one application of thirty minutes duration was made. Three hours later, severe abdominal pain with marked tenderness ensued, with a rise of temperature to 104, typical signs of acute pelvic peritonitis, and an abscess formation that necessitated posterior colpotomy. Another patient who had a severe postabortum pelvic infection and general peritonitis was given one diathermy treatment. This patient's condition was made worse, and she died shortly following the application. A third patient who had abdominopelvic masses of an obscure origin was given two diathermy treatments. The pain was increased in severity, and the masses increased in size. An abdominal section and pathologic examination revealed an actinomycosis of the abdominal parietal peritoneum. She made a good recovery.

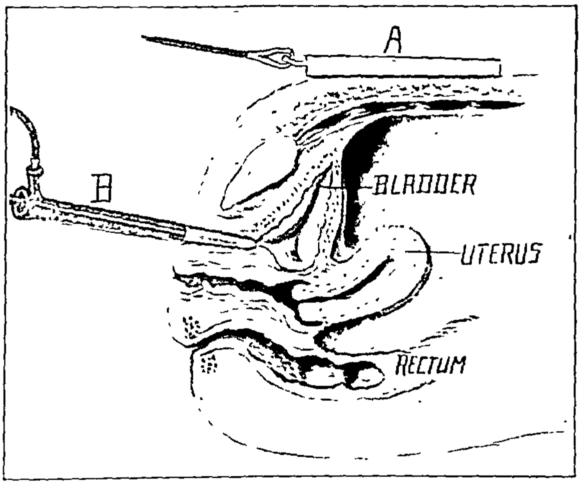

Fig. 6.—Application of Corbus thermophore, *B*, for gonorrheal urethritis; *A*, abdominal water-cooled electrode.

The specific bacteria responsible for most postpartum infections are the streptococcus, staphylococcus and the *colon bacillus. These bacteria require from 58 to 60 C.* of heat to render them inert. In view of the experiences I have described, I am led to conclude that when a much lower degree of heat is applied in the presence of such infections, not only does it fail to inhibit the pyogenic process, but also it produces a suitable cultural environment for the bacteria, and probably serves as a revivifying agent, which may incite an acute inflammatory process. It is true that these postpartum infections were acute in one case and subacute in the others. What the effect of diathermy would be in the chronic type of postpartum exudates is open to question.

CONCLUSION

I would venture to assert that diathermy is probably the most satisfactory available agent for the conservative treatment of pelvic infections due to the gonococcus. It relieves pain, diminishes the pelvic masses, and aids in complete resolution. Used as a preoperative therapeutic measure, it will eliminate many of the technical difficulties in the removal of large pelvic masses, and thereby contributes to a smoother convalescence. Incidentally, the percentage of postoperative wound infections is lessened.

580 Park Avenue.

ANKYLOSING OPERATIONS ON THE TUBERCULOUS SPINE

A STUDY OF FIFTY-THREE CASES*

LEONARD W. ELY, M.D.
SAN FRANCISCO

I have collected the histories of the patients with tuberculous spines who were operated on in the orthopedic clinic of Stanford University during the last twelve years, and to them I have added the histories of my private patients. A synopsis of the cases is given in the accompanying table.

The evaluation of any form of treatment is largely a personal matter. One who is content with an inspection of the outside of the body and never troubles to follow his cases to the mortuary and the laboratory can believe in the efficacy of any form of treatment. There are those who think that they can cure spinal tuberculosis by exposing their patients to sunlight. Twenty years ago, the same extravagant claims were made for the seashore of northern France as are made today for the sunlight in the mountains of Switzerland. My patients at the Sea Breeze Hospital at Coney Island, kept in the open air, were in excellent condition, but the course of their disease was not materially changed. Much the same may be said of the outdoor treatment carried out in any good climate. We are asked to believe that the sun's rays at a particular spot in Switzerland possess peculiar therapueutic virtue. I have never been able to detect any specific influence of California sunshine.

Until about twenty years ago the nonoperative treatment, by plaster of paris, by braces and by frames in recumbency, was practiced almost universally by those who treated many cases of spinal tuberculosis. No successful operation had ever been devised. Orthopedic surgeons stressed the value of these measures, and carried them out with meticulous care. Many of them follow the same course to this day. I was brought up in this school, and practiced the treatment for years. I worked in the clinics and hospitals of New York, enthusiastically at first, but with slowly lessening hopefulness, for about fifteen years. In all that time, watching other men's patients as well as my own hundreds of cases, I did not see as many cures as I have turned out in the fifty-three cases reported here. We would treat our patients for from two to five or more years, perhaps discharge them as cured, and then meet them in another clinic, or perhaps have them report back to us after a longer or shorter time, with a recrudescence of their disease. Such a thing as a cure without serious deformity was almost unknown. In spite of most painstaking care, we would be obliged to watch the development of an enormous hump. In the old days, we regarded Pott's disease in the adult as practically fatal. Occasionally, children recovered, but always with a large hump, which advertised the nature of their affliction to all throughout life. One seldom sees a typical "humpback" nowadays.

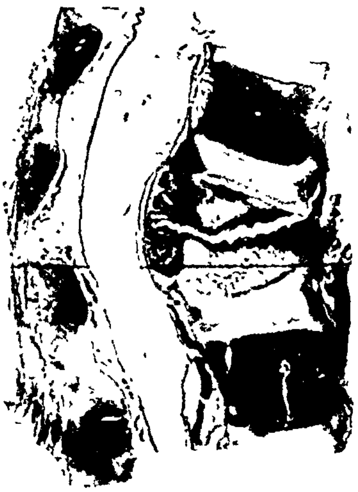

Fig. 1.—Stained slide of sagittal section of tuberculous lesion, comprising an epitome of spinal tuberculosis. Death occurred about six months after operation from intercurrent disease. The disease is in the stage of repair. The vertebra shows much calcification. The wedge shape, the bony bridge in the laminae, the trace of a cold abscess forming anteriorly, the tuberculous granuloma, under the posterior common ligament, bulging this out, and comprising the lumen of the spinal canal, may be noted. (Case of Dr. James T. Watkins.)

In spinal tuberculosis, as in other diseases, a choice of two methods is available in seeking a cure. By abstract reasoning one may evolve a theory, and then try it out on one's patients. This is pure empiricism, and is slow and uncertain. Its permanent good results in medicine can be counted on the fingers. Heliotherapy, drug treatment and external applications rest on this base. The other method is to accumulate facts, and then to attempt to reason from them to a cure. Let us apply this method to joint tuberculosis.

The cardinal symptoms and physical signs of joint tuberculosis are pain made worse by motion, muscular spasm, muscular atrophy, limitation of motion, and deformity in the sense of flexion contractures and subluxation. All these may be interpreted best as nature's effort to put the joint at rest. When we take the trouble to examine our specimens in the laboratory, we see the concrete evidences of this effort on nature's part. The tuberculous granulations in the bone marrow seem almost infallibly to seek the joint with a well defined purpose—to destroy it. The cartilage is perforated and killed; the granulation tissue unites with that from the other bone of the articulation and with that from the synovial membrane. The synovial membrane becomes thickened, and eventually little else but scar tissue. The joint becomes a mass of scar tissue, and as a working organ of motion is hopelessly injured. However, it is very rarely completely destroyed. Bony ankylosis is seldom if ever seen. Nature appears unable to form it in the absence of a secondary infection. Abscess formation, with secondary pus infection, is a frequent complication of joint tuberculosis. The joint then may be completely destroyed, but the risks of the disease are multiplied many times. The danger to life is great. The patient dies while nature is endeavoring to cure his disease. We note further that in the fibrous tissue in and about the joint, tuberculous foci may exist indefinitely, ready at any time to resume activity if they are set free, accidentally or with design.

---

* Read before the surgical section of the San Francisco County Medical Society, Feb. 16, 1926.

We must throw out all the wild claims of wonder cures, and lay down our main rule of treatment, which is to deprive the joint of function.

How far shall we go in following this rule in the treatment of spinal tuberculosis? The nonoperative treatment is uncertain, takes years of time at best, and almost always is followed by marked deformity. Dissatisfaction with it, be it remembered, spurred orthopedic surgeons to devise something better, until Hibbs and Albee succeeded in ankylosing the spine. Hibbs got his idea from his observation of the fusing of the spinous processes in old specimens of spinal tuberculosis. In operating in such cases, one often notes this to a greater or less extent.

In the operative treatment, all the work is done on healthy bone, and at a considerable distance from the tuberculous portion. Hence, no danger of secondary infection exists. There remains, then, it seems to me, only the direct risk of the operation. This is very real without a skilled anesthetist. With one, it is almost negligible. We lost two patients on the table in our early work, the history of one of whom I have lost. We published the history of these two. Few other fatalities have been published, unfortunately. I have reason to believe that there have been many others.

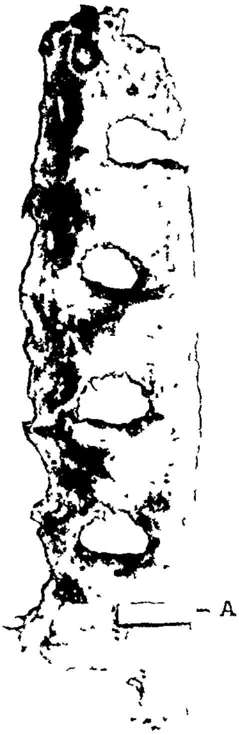

Fig 2 — Specimen showing result of Albee operation Patient died four years after operation, from hepatic cirrhosis Necropsy showed disease in stage of healing *A* section of graft and spinous process removed for study (Dr McChesney's case)

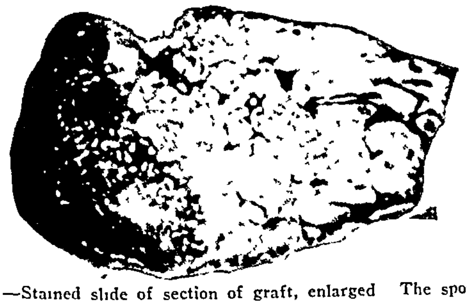

Fig. 3 —Stained slide of section of graft, enlarged The spongy bone is the spinous process

The patient should be anesthetized on his face in a comfortable attitude, with cushions arranged so that his breathing will be unimpeded. When the operation is finished, the patient is rolled carefully onto the ambulance, and remains flat on his back for about a week before his wound is dressed. He is kept in recumbency for six weeks, though he may lie on his side or on his face after the first week. After this, he wears a spinal brace for about six months. Theoretically, a brace is not necessary after the establishment of the bony bridge, but we never know when the bridge is strong enough to support the strain to which it is exposed.

We prefer the Hibbs operation to the Albee, though it is much more difficult to perform. Theoretically it is better, for the bony bridge, once formed, is permanent, while anything may happen to a graft, sooner or later. On the other hand, the Albee operation is excellent in an early case in which the disease seems to be localized in one or two vertebrae. It is quickly done. I fancy it for lumbar disease. The disadvantage of the Hibbs operation is the frequent failure to establish bony union between two or more of the vertebrae operated on. Our statistics show a heavy percentage of second operations. The presence of one or more places of nonunion can be told by the persistence of symptoms, though it may be inferred from the roentgenograms. It is annoying to be obliged to do a second operation, but we almost always find the false joint when we do it. No one should assume an air of superiority in this matter. I have done the second operation on other men's patients as well as on my own. In some cases the operation fails because it has not been carried high or low enough.

The Hibbs operation is a poor one to do before the class. It requires careful dissection. When we attempt to hurry, we get into trouble.

The results of these operations, as to the deformity, are good. Usually, with proper postoperative splinting, the increase of the deformity is checked. Once in a while it goes on slowly increasing for a number of years, but not to any great extent. This is usually in disease of the thoracic region, in which already existing deformity puts too great a strain on the new bone.

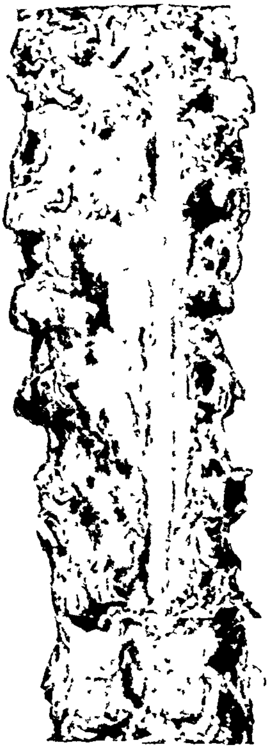

Fig 4 —Posterior aspect of spine in case 20, showing the bony bridge in the laminae, and its reinforcement by a bone graft

In cases with secondarily infected tuberculous abscesses, the outlook is not particularly promising, but we have cases of recovery on record, one or two of them in adults. I think our statistics would be more brilliant if we picked our cases carefully, but we take them as they come. If the patient is able to stand the operation, and has no discharging sinus near the field of operation, we operate. Operation was adopted as the treatment of choice shortly after the orthopedic department was opened at Stanford some twelve years ago. At first in the case of young children, we tried nonoperative treatment, and operated only when this did not seem efficacious. Now we operate on patients of all ages.

Unlike the diagnosis of tuberculosis of other joints, the diagnosis of spinal tuberculosis is usually a tentative one. We are never absolutely sure of our ground, and our results might be questioned on this account. How-

Data in Fifty-Three Cases of Tuberculosis of the Spine Occurring in Clinical and Private Practice

No	Date	Age	Sex*	Location	Complication	Operation	Result	Comment
1	1914	3	♂	7 T (abt)		Hibbs	Death on table	
2	1914	4	♂	1, 2 L		Hibbs	Cure	Well, December, 1925
3	1915	5	♂	"lower T"	Tuberculous tarsus	Hibbs	Cure (1926)	Cure of tarsus also
4	1915	6	♂	T - L		Hibbs	Cure (December, 1925)	Operation done as last resort; child in very bad condition; second operation one year later
5	1915	6	♀	10 12 T, 1 L		Bone grafts	Cure	This was a second operation; a Hibbs had previously been attempted
6	1916	3	♀	6 T		Hibbs	Cure	Bony bridge demonstrated at second operation
7	1916	26	♂	1 3 L	Psoas abscess; tuberculous epididymitis; tuberculous rib	Albee	Failure	
8	1916	21	♂	12 T		Albee	Well one year later	
9	1916	8	♀	12 T 1 L		Albee, 2, Hibbs	Cure	First operation not extensive enough; second operation enlarged area upward
10	1916	5	♂	2 L		Hibbs	Cure	Died of tuberculous meningitis seven years later following mastoid disease
11	1917	18	♂	11 T - 1 L	Tuberculous tarsus	Hibbs	Cure	Tarsus also well in 1925
12	1917	30	♂	4 L	Pulmonary tuberculosis	Albee	Failure	The graft broke during the operation; patient unruly afterward
13	1917	31	♂	7 - 10 T		Hibbs	Death, meningitis, six weeks postoperative	
14	1917	23	♂	1 L		Albee	Presumably well in 1919	*Cannot be found in 1926*
15	1918	12	♂	3, 4 L		Hibbs	Cure	Operation on tuberculous hip four years later; death from mixed infection of hip in 1924
16	1918	8	♂	3 - 5 L.		Hibbs	Cure	Reported as cured in 1924, but not examined
17	1918	9	♂	7 C - 2 T		Hibbs	Cure (one year later)	Cannot be found for examination; in 1925, said by a friend to be well
18	1918	26	♂	12 T - 1 L	Infected lumbar abscess	Albee, 2 operations	Unknown	First operation did not extend low enough
19	1918	28	♂	10 - 11 T		Albee	Failure	
20	1918	4	♂	10, 11 T	Tuberculous sternum	Hibbs, second operation, bone graft	Death, tuberculous meningitis 8 months postoperative	Specimen showed bony union at operative site
21	1919	35	♂	8 10 T	Tuberculous metaphal positive guinea-pig test	Hibbs	Unknown	*Cannot be found*
22	1919	28	♀	12 T, 1 L	Paraplegia	Albee, second operation Hibbs	Unknown	Aspiration of cold abscess gave positive guinea pig test
23	1919	34	♂	2 5 C		Albee	Cure, 1922	Cannot be found in 1925
24	1920	25	♂	4 L		Albee	Unknown	
25	1920	30	♂	3 L		Albee	Unknown	
26	1920	26	♂	5 L	Large infected abscess	Hibbs	Death 18 months postoperative	Patient died from effects of prolonged suppuration
27	1920	32	♂	2 - 3 L	Tuberculous rib, lung and epididymis	Hibbs	Cure, 1926	
28	1920	38	♂	5 L		Hibbs	Cure, 3½ years postoperative	Cannot be found in 1926
29	1920	21	♂	L S		Hibbs	Cure	
30	1920	16	♀	2 5 L		Hibbs, two operations	Cure	Second operation necessary in 1925
31	1920	24	♀	4, 5 L	Psoas abscess, which later broke down and became infected	Hibbs	Abscess still discharging in 1925	
32	1921	5	♀	9 - 12 T.		Hibbs, three operations	Cure	
33	1921	19	♂	7 9 T		Hibbs	Unknown	
34	1921	27	♀	4, 5 L, 1 S		Hibbs, Albee	Failure	A joint persisted between 5 L. and 1 S. after first operation
35	1921	?	♂	4, 5 L	Infected abscess, plus tuberculous tarsus	Hibbs	Unknown; dead in 1926	
36	1921	35	♀	4, 5 L		Hibbs	Cure	Cure reported by letter, but no examination in 1925
37	1921	9	♂	7 - 9 T		Hibbs, 2	Unknown	Second operation two years after first, for persistence of symptoms
38	1921	42	♀	7 T		Hibbs, 2	Cure	Second operation for persistence of symptoms
39	1921	5	♀	3, 4 L.		Hibbs, 2, plus graft	Cure	Second operation for persistence of symptoms
40	1922	4	♂	5, 6 C		Hibbs, 2	Cure	Second operation for persistence of symptoms
41	1922	22	♂	1, 2 L		Hibbs	Cure	
42	1922	21	♂	4, 5 T.		Albee	Unknown	
43	1923	13	♂	2, 4 L,		Hibbs	Cure	
44	1923	18	♂	12 T. - 2 L	Infected abscess	Hibbs	Improved	Great deformity; suppuration for seven years
45	1923	13	♀	2 - 4 L.	Infected abscess	Hibbs, 2	Cure ?	Reported well in 1925, but not examined
46	1923	34	♂	7 - 9 T		Hibbs	Unknown	
47	1923	23	♀	10 - 12 T.	Tuberculous tarsus, tendovaginitis, and finger	Albee	Death	Meningitis, seven weeks after operation
48	1924	14	♀	8 - 10 T		Hibbs	Cure ?	Examined one year after operation
49	1924	5	♂	3, 4 L	Infected abscess	Hibbs	Unknown	Suppuration said to be still going on
50	1924	28	♀	4, 5 L		Hibbs	Cure	Last examined one year after operation
51	1924	38	♂	5 L		Hibbs	Cure	
52	1924	2	♀			Hibbs, 2	Cure	Second operation for persistence of symptoms
53	1925	21	♂	2, 3 L	Enormous psoas abscesses	Hibbs	Cure	

* In this column, ♂ indicates male; ♀, female.

ever, the roentgen-ray picture is fairly conclusive. Fracture gives a different history, and the film shows a crushing rather than a destruction of the bone. In coccidioidal granuloma, the lesions are wont to be multiple, and the oidium can be recovered sooner or later in the pus. It is rare at best. Syphilis can usually be excluded, with care. A syphilitic lesion would tend to grow worse without the appropriate treatment, and quickly better with it, and would not be affected by any operation.

In quite a number of our cases we have obtained strong presumptive evidence from the demonstration of tubercle bacilli in the pus from a cold abscess, by guinea-pig inoculation. Against this, one might argue, of course, that we were not sure of the connection of the abscess with the spine.

In several of the cases, a paraplegia has disappeared after the operation. Indeed, occasionally the improvement sets in almost immediately. On the other hand, one of our histories indicates that a paralysis supervened on an Albee operation. The paralysis is almost always caused by granulation tissue under the posterior common ligament, pressing on the anterior columns of the cord, not by bony pressure, and activity of the process seems to be necessary for the continuance of the paralysis.

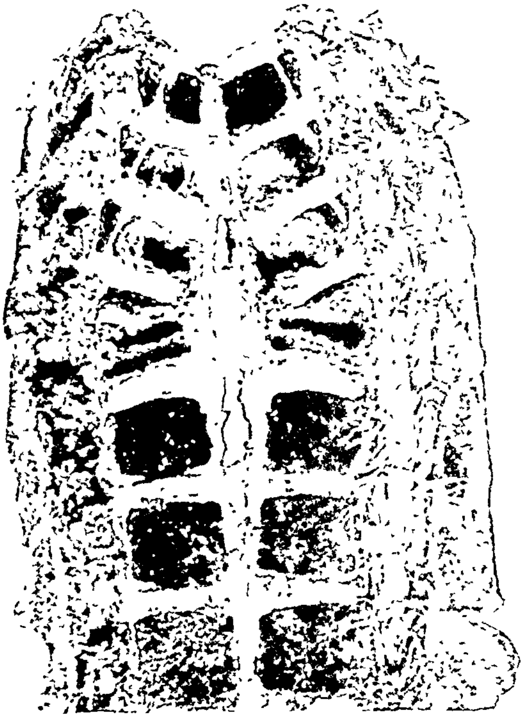

Fig. 5.—Spine in case 20 laid open from behind. The wedge shape betrays the identity of the vertebra first involved In spite of the extensive involvement of the two cephalad vertebrae, the bony bridge keeps them from collapsing. No signs of healing can be seen.

When we speak of a cure after operation, we do so with a reservation. Patients are not cured as they are after a successful appendix operation. The focus of infection remains indefinitely, perhaps throughout life. I have one specimen showing well marked calcification of the lesion, and another without any evidence of repair. In both, the spine was firmly ankylosed. The most we can accomplish is to bring the disease to a standstill.

Tuberculosis of the spine indicates a lack of resistance of the patient to the tubercle bacillus, and the presence of a tuberculous lesion somewhere else in the body. It is not to be wondered at that many of the patients die early. Their death is not to be charged against the spinal operation, and often not to the spinal disease itself. Several of our patients died of meningitis, but only one after so short an interval as to justify a presumption of cause and effect.

In the old days, cold abscesses formed and increased in size during careful treatment with plaster of paris or braces, necessitating prolonged rest in bed. In none of our cases did this occur after the formation of the bony bridge. This is, perhaps, one of the strongest arguments for operative treatment. It stops activity when the nonoperative treatment evidently failed. When, after operation, roentgenograms showed the formation of an abscess or the increase in size of an already present one, a second operation showed that the bony bridge was not complete or was not extensive enough.

CONCLUSION

A rational explanation of all the symptoms and physical signs of joint tuberculosis is that they are nature's effort to put the joint at rest. Laboratory investigation confirms this. Our experience in the orthopedic clinic at Stanford is that spinal tuberculosis *is no exception to the general rule.* An ankylosing operation should be done on patients of all ages, whose general condition permits it. If the operation is not successful, it should be revised. The reason for failure will usually be found to be a break in the bony bridge. The greatest danger is unskilful anesthesia.

Clay and Webster streets.

SPOROTRICHOSIS

REPORT OF TWO CASES

RALPH M. CARTER, M.D.
GREEN BAY, WIS.

While sporotrichosis can no longer be considered a rare disease, in view of the number of cases which have been reported with increasing frequency during the last few years, the condition is sufficiently uncommon to justify putting additional cases on record, particularly if they occur in a region in which it has heretofore been absent, or at any rate unrecognized.

In the last few months, two cases of the disease have come to my attention, both originating in this section of Wisconsin. I have searched the literature of the subject fairly thoroughly, and have been able to find reports of only two additional cases from this state. One of these is mentioned in an article by Meyer,[1] in 1915, and was not verified by culture; the other was described in detail by Baer,[2] in 1920. While the organism cultivated from the latter case differed slightly in some respects from the one usually found, nevertheless typical lesions were present, and there is no doubt that the case was one of true sporotrichosis.

REPORT OF CASES

My two cases may be briefly described:

Case 1.—A rural mail carrier, referred to me by Dr. Frank Wochos of Kewaunee, Wis., July 1, 1925, aged 38, gave a previous history which contained nothing of any significance. The general physical examination was negative. About two months previous to consulting me, while transplanting some shrubbery in his yard, he scratched the right middle finger at the base of the nail on the thorn of a barberry bush. He paid no attention to it at the time, but at the end of a week or so the apparently insignificant laceration showed no signs of healing; on the contrary, it seemed to be getting larger, and in addition a red, painless swelling had appeared on the dorsum of the hand. He treated the original lesion with poultices, ointments and various home remedies, with no effect whatever, as it continued to get worse. During this time more red, nodular swellings had appeared on the hand and forearm. He now sought medical advice, and consulted several physicians in turn. None of them apparently recognized the true nature of the disease, but considered it an unusual form of infection with a pus organism, with an ascending lymphangitis. He was advised to treat it by means of hot fomentations, which he did, with no improvement. More nodules continued to appear on the arm, and the original lesion showed no tendency toward healing. The nodules appeared first as painless lumps in the subcutaneous tissue; gradually the skin over them became a dusky red; the nodules finally became fluctuant and somewhat painful, and some of them opened spontaneously, exuding a thick, gelatinous pus and leaving a small, superficial ulcer, with somewhat undermined edges; this ulcer would slowly heal, leaving a brownish pigmentation of the skin.

[2] Baer, C. A.: Sporotrichosis: Report of a Probable Case, Wisconsin M. J. **18**: 375 (Feb.) 1920.

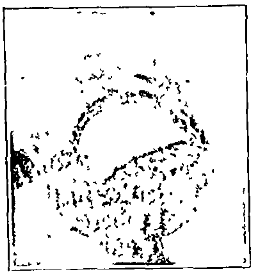

Fig 1 (case 1). — Primary lesion, or sporotrichotic chancre

The appearance of the primary lesion, or sporotrichotic chancre, as it is sometimes called, at the time of my first examination, is fairly well shown in figure 1. The entire end of the finger presented a raw, ulcerated appearance, with exuberant granulations and many small abscesses, from which a yellow pus exuded. The nail was loosened, and pus could be expressed from beneath it. The appearance of this primary lesion presented a superficial resemblance to cutaneous blastomycosis, although there was not the tendency to central healing, and the abscesses were larger.

The nodules on the forearm and upper arm are shown in figure 2. These were in all stages of development: some were not yet visible but could be palpated as hard lumps in the tissues; others were dusky red, slightly elevated and hard; still others were soft and fluctuant, apparently ready to open. Constitutional symptoms were entirely absent, and had been so since the beginning.

Smears were made from the pus from the original lesion, but revealed only pus cells and staphylococci. Cultures of this pus likewise produced nothing but staphylococci. Pus aspirated from one of the unopened nodules showed no characteristic organisms when examined in the smear, but cultures on glucose agar told an entirely different story. The growth was slow in appearing, nothing being visible until the sixth day, when small, white, circular colonies having a rayed appearance developed. These gradually increased in size, the surface becoming corrugated and brownish to almost black. Films and hanging drop preparations from these cultures showed long filaments with numerous ovoid spores. Here and there could be seen single spores, and also bunches of from twenty-five to thirty attached to the filament by a short pedicle or stem. The appearance of a slide is shown in figure 3. The organism corresponded in every detail with *Sporothrix schenkii,* and definitely established the diagnosis.

The patient was immediately put on increasing doses of potassium iodide, and complete recovery promptly followed.

Case 2.—A general storekeeper, aged 45, seen in consultation with Dr. O. W. Saunders of this city, was of the opinion that sometime previously he had scratched his right middle finger on a packing box, though the history of the original trauma was somewhat indefinite. He likewise had been through several hands before we saw him, without the nature of the disease being recognized. The condition present when I saw him was exactly the same as in case 1; having this patient under treatment at the same time, I made the diagnosis with no difficulty; however, cultures were made, and proved positive for *Sporothrix schenkii.* Prompt and complete recovery followed the administration of potassium iodide.

REPORTS IN THE LITERATURE

Sporotrichosis, recognized as a definite entity, is a disease of comparatively recent date, the first case having been reported in America by Schenk[3] in 1898. This was followed in 1900 by the report of another case by Hektoen and Perkins.[4] In 1903, de Beurmann's[5] original report dealing with French cases appeared. Following this, cases began to be reported from all over the civilized world, and the literature of the subject grew rapidly. In 1912, Hamburger[6] stated that more than 200 authentic cases were on record at the time, and since then many additional ones have been reported.

CLINICAL VARIETIES

While the disease usually appears as a cutaneous manifestation, it is by no means confined to the skin structures, and apparently no part of the body is exempt. The frequency with which the skin is attacked is probably accounted for by the usual mode of infection, as a result of minor peripheral traumas. According to de Beurmann,[7] four clinical varieties of the disease may be recognized.

1. A localized cutaneous form, with a definite primary lesion, or sporotrichotic chancre, together with an ascending lymphangitis and local lymphadenitis. The cases reported in this paper belong to this variety.

2. A disseminated, gummatous form. In this variety, multiple subcutaneous nodules appear, distributed throughout the body without systematic arrangement; in the early stage, these consist of small, hard, round, painless masses; later they soften to form large and small soft cold abscesses. A distinguishing feature is the fact that there is no ulceration.

3. A disseminated ulcerative sporotrichosis. This is characterized by multiple polymorphic ulcerations resembling tuberculous, syphilitic, ecthymatous, rupial or furuncular lesions, or a mixture of these.

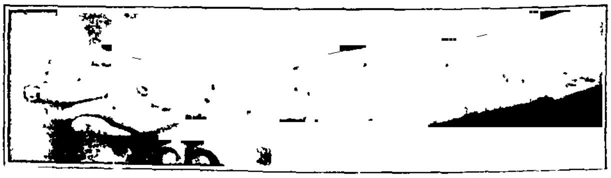

Fig 2 (case 1).—Sporotrichotic nodules of hand and arm.

4. Sporotrichosis affecting the extracutaneous tissues. In these cases, localization may be in the mucous membranes, bones, joints, ocular tissues, muscles, synovial membranes, kidneys, lungs or other viscera or tissues.

THE ORGANISM

The disease is due to infection with *Sporotrichum,* a fungus. When the condition first began to be studied, it was believed that different manifestations were due to different varieties of the organism, and various strains were described, as, for example, *S. schenkii*, *S. beurmani* and *S. dori*. Later investigations, however, seem to have established the identity of all these as *S. schenkii*, the morphologic differences formerly noted as characteristic of different varieties all appearing at different ages of *S. schenkii*, as mentioned by Taylor.[8]

[7] De Beurmann: Brit. M. J., 1912, p. 289.

In certain parts of the United States, especially Pennsylvania, Ohio, Indiana, Iowa, Nebraska and North and South Dakota, spontaneous sporotrichosis of domestic animals, particularly horses, is very common. From the same districts, numerous cases of human infection have also been reported, and it has been definitely determined by Meyer[1] that the infecting organisms in the equine and human types are identical. In spite of this fact, it seems to be fairly well established that contact infection from animals to man is very rare.

The fungus seems to have a rather wide distribution in nature, being present especially on shrubbery and grain stalks. Several cases of infection have occurred from the handling of rotten logs and stumps, when new land is being cleared.

The organism is practically never found in the pus from discharging abscesses; cultures from these abscesses are likewise unsatisfactory. It is readily grown, however, from pus obtained by aspiration from an unopened nodule.

The fungus grows on all ordinary mediums, best in the presence of glucose and slight acidity, at room temperature. One of the most satisfactory is 2 per cent glucose agar. The growth is slow in appearing, and nothing may be noted for from five to seven days. At the end of this time, on agar slants, small, white, circular colonies appear, which rapidly enlarge peripherally, and assume a rayed appearance; in stabs, the growth has a radiating, flower-like appearance. The colonies become raised, and the surface corrugated, and as the growth gets older, it is brown to brownish black. Subcultures from the original culture have a tendency to grow much faster, the colonies appearing within forty-eight hours.

The organism stains readily with the ordinary stains, such as Loeffler's methylene blue, azure, Giemsa's and methyl thionin. In many cases, according to Taylor, the spores and young mycelia are gram positive and acid fast.

A suitable preparation, examined microscopically, shows aboundant branching, septate mycelial threads and numerous ovoid, pea-shaped spores. These spores may appear attached laterally to the mycelium by a delicate pedicle, or in clumps at the ends of the short threads. In the older cultures, free spores are numerous.

The disease may occur at any age, but the majority of the cases reported are in adults, undoubtedly because this is the time of greatest manual activity, with consequent greater likelihood of infection. For the same reason, more men acquire it than women. Cases are more numerous among farmers, fruit and vegetable dealers, berry pickers and florists.

In the ordinary cutaneous form, which is most frequently encountered, infection usually follows a trivial trauma, such as a scratch from a nail or wire, a knife cut, or a prick from a thorn or stalk of grain. Cases are reported following the bite of a rat or hen. The period of incubation is slow and the onset insidious; more and more nodules form, following the course of the lymphatics; the clinical course is slow and long drawn out; there is no pain or fever, and no effect on the general health. All these characteristics are typically shown by the two cases reported in this paper.

Occasionally, the deeper structures such as the tendon sheaths, and even the bones may be attacked; or a sporotrichotic septicemia may occur, with multiple gummatous lesions of the skin and viscera.

Microscopically, according to Taylor, the lesions are granulomatous in appearance. The center is usually necrotic; surrounding this is a zone of dense cellular infiltration, with polymorphonuclear cells predominating; outside the latter zone is a large area of congestion, hemorrhage and infiltration of large eosinophilic cells, with marked proliferation of connective tissue and frequent giant cells. The spores of the organism can be demonstrated in the lesions, more numerous at the periphery of the necrotic area, but distributed throughout, and usually intracellular. The mycelium cannot usually be satisfactorily demonstrated in the lesions.

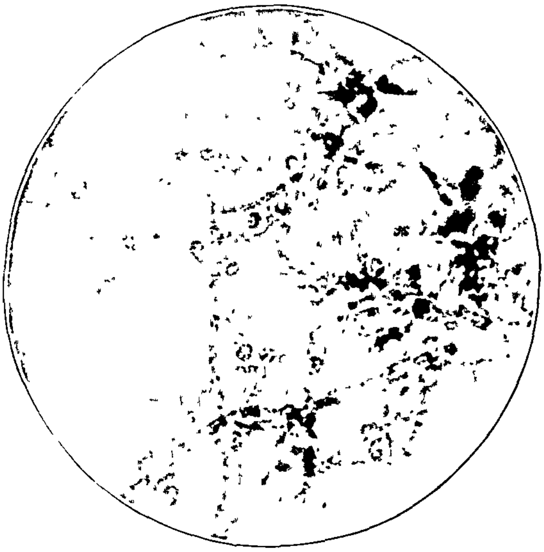

Fig 3 —Stained preparation from culture showing mycelia and spores; × 1,200

DIAGNOSIS AND TREATMENT

The diagnosis, in the form of sporotrichosis most frequently encountered, that affecting the extremities, is not difficult after the case has developed and the nodules have formed, as the disease presents a characteristic appearance. Under these circumstances, the only other condition likely to be confused with it is an acute ascending lymphangitis and lymphadenitis; but such an error would be excusable only if no opportunity were given for examination other than mere inspection. It is true that both conditions present the picture of red streaks and enlarged lymph nodes secondary to an infected wound, but here the resemblance ceases. In sporotrichosis, the wound of entrance presents an entirely different appearance; the streaks are more pronounced, the glandular nodules, in addition to being palpable, are visible as dusky red swellings and are more numerous; the history shows a prolonged course, and pain, disability and constitutional symptoms are conspicuous by their absence. All this forms a clinical picture that is difficult to mistake for anything else, and a highly probable diagnosis can be made from the physical examination alone, which is rendered positive by the presence in the blood of an agglutination reaction for *Sporotrichum*, and later, by the cultivation of the organisms from pus obtained under sterile precautions from one of the unopened nodules. The presence of an eosinophilia, while confirmatory, is of no real diagnostic significance, since it occurs in many other conditions.

---

[8] Taylor, Kenneth: Sporotrichum Schenkii, J. A. M. A. 60: 1142 (April 12) 1913.

Other forms and modifications may present more difficulty. The primary lesion, or chancre, strongly resembles cutaneous blastomycosis; it differs, however, in that the abscesses are larger. There is not the marked tendency to central healing; large crusts do not form, and the peripheral local spread of the lesion is slower. Likewise, cutaneous blastomycosis does not give rise to the lymphangitis and lymphadenitis so characteristic of sporotrichosis. With involvement of the deeper structures and bones, with the tissues riddled with sinuses, as sometimes occurs, and with the extensive secondary infection always present after the nodules have opened, the picture is far from typical. In such a case, tuberculosis may enter into consideration; in fact, it may occasionally be present. Under certain circumstances, too, it may become necessary to rule out syphilis and epithelioma.

Having the salient features of the disease and the possibility of its occurrence in mind, however, with a little care the diagnosis should offer no insurmountable difficulties. Naturally, a careful history of the disease from its inception should be taken; the occupation of the patient, the nature of the original trauma, the insidious onset and slowly progressing course of the disease, whether or not it has shown any effect on the general health, all these points are important, and throw light on the condition present, so they should be carefully considered. No reliance can be placed on a fresh smear from the lesions; in most cases the organisms cannot be demonstrated; cultures should always be made, and with these cultures, the agglutination test can be carried out. I wish to emphasize once more that the material for cultures must be taken from the unopened nodules; secondary invaders are always present in the primary lesion and in the open nodules, and no growth of *Sporotrichum* will be obtained from pus from these sources.

The treatment is simple, and consists in administering increasing doses of a saturated solution of potassium iodide. Local applications of compound solution of iodine (Lugol's solution) may hasten the disappearance of the primary lesion. Under this management, the patients all recover.

Silicosis.—As an aid to physicians in the state of New York in diagnosing cases of silicosis, Dr. Leland E. Cofer, director of the bureau of industrial hygiene of the New York State Department of Labor, has had prepared a special bulletin in which is presented a summary of the medical literature with especial reference to diagnosis. The bulletin states: Careful studies which have been made of the mortality reports of different countries and cities throughout the world show that the death rate from tuberculosis of the lungs greatly varies. Silicosis is not a well known disease and has not, therefore, been entered on the death certificate as a cause of death, but rather, the terms phthisis pulmonalis, fibroid phthisis or tuberculosis of the lungs have been used. The term "phthisis" is unfortunate, unscientific and, as the statistics show, has been misleading. The sooner it is expunged from the vocabulary of the physician the better it will be, not only for the value of the records, but also for the workers in dust and the reputation of tuberculosis.—*Pub. Health Rep.* **41**:521 (March 19) 1926.

ISACEN (GUGGENHEIM): A NEW PURGATIVE *

MAX EINHORN, M.D.
AND
HENRY A. RAFSKY, M.D.
NEW YORK

Modern pharmacology is not satisfied with the manufacture of remedies from roots and plants, but tries to obtain the specifically acting principles in pure form. It also tries by new synthesis to produce remedies that act more favorably than those found in nature.

Guggenheim[1] was very much interested in the investigations of Lenz,[2] and developed a new remedy based on them. Lenz made extensive experiments on cats in which an abdominal window was established, so that different remedies could be studied with regard to their action on the intestinal tract. He found that most of the aperient remedies exerted their action by exciting the peristalsis of the colon, when coming into contact with this organ. The effect on the intestine of an extract of senna leaves, or of the different ingredients contained in it as a mixture of anthrachinon derivatives (as anthrachinon glucosides, emodin and chrysophanic acid), consists in provoking peristaltic action when the latter is applied to it. There is, however, some slight difference in the mode of action if each of the foregoing ingredients is applied separately. Phenolphthalein belongs to the same group of substances and acts in a similar manner.

The cause for this difference in the action of the remedies mentioned is explained by Guggenheim through their different degree of acidity and also by their different quality of solubility. On the whole, all combinations whose acidity is less than that of phenolphthalein act weaker than this ingredient, while those substances which have a greater acidity act more efficiently on the intestinal peristalsis.

There is, however, a certain point of acidity which marks the optimum of efficiency above which again the effect changes into inactivity, so that no laxative action results.

Guggenheim synthetically produced a substance similar to the foregoing ingredients, namely, bisoxyphenylisatin, which has a slightly higher acidity.

Guggenheim thought that theoretically this substance would act well as an aperient. In experimenting on himself he found that it really had a laxative effect. However, this substance had the disadvantage that it was slightly soluble in the gastric juice and in this way exerted its action by provoking the peristalsis of the stomach. This untoward early action causes at times nausea and vomiting and thus detracts from its value as a laxative remedy. By changing this substance into a compound which is obtainable by acetylization of bisoxyphenlyisatin, he obtained a new chemical, diacetylbisoxyphenylisatin, which he called isacen.

Isacen is insoluble in acids or water. In this way it cannot be absorbed in the stomach and cannot exert any action while present in this organ. When isacen comes into contact with the alkaline secretion of the duodenum, it is saponified and splits into bisoxyphenylisatin, and in this way can now exert its action on the bowels.

---

* Because of lack of space, a table and the structural formulas are omitted from The Journal. The complete article appears in the authors' reprints.

[1] Guggenheim, M.: Die spezifische Kolonwirkung der Abführmittel und ihre Abhängigkeit von der chemischen Konstitution, Schweiz. med. Wchnschr. **55**:16 (Jan. 1) 1925.

[2] Lenz: Observations à la fenêtre abdominale colique du chat, Arch. internat. de pharmacod. **28**:1, 1923.

Guggenheim first tried this new substance on himself. He took 5 mg. from two to four times daily and found that it acted as an aperient without any untoward results.

Katzenelbogen and Guder [3] have tried isacen on many patients in their clinics and corroborate Guggenheim's findings.

On account of the importance of a remedy for constipation, which is such a prevalent condition, we decided to investigate the action of isacen on patients and to study its results.

We made these investigations on private patients and in the Home of the Daughters of Jacob. The inmates of the latter institution are persons aged from 60 upward. Most of them are subject to constipation and rather more difficult to handle than young and healthy subjects, and for this reason they appeared especially appropriate to decide whether or not isacen can be considered a useful remedy for constipation. The accompanying table gives the results of the investigation.

The table contains records of forty-seven patients who took isacen for a whole month. Tablets containing 0.005 Gm. were given two, three or four times daily. In thirty-nine patients nothing else was required to keep the bowels tolerably regular. In eight of the remaining patients an enema or epsom salt was given on some days, while on other days the isacen was sufficient to produce an evacuation of the bowels. Twenty-eight of the forty-seven patients were entirely free from pain or colic while using isacen. Of the remaining nine patients, one had severe pain before and during defecation, while eighteen experienced occasionally some pain either before or during defecation.

The number of movements fluctuated from one to two, seldom three or four a day. Occasionally there would be no movement for a day or two in some of the cases.

All the forty-seven patients were more or less chronic invalids. Four had diabetes. Four had chronic nephritis; nine, paralysis agitans; nine, general arteriosclerosis; two, senile dementia; three, chronic constipation of a severe type; two, tuberculosis of the lungs and pharynx; seven, chronic myocarditis; two, general debility, and one, chronic gastritis.

A laxative remedy will certainly be more efficacious in healthy persons than in invalids. Isacen has proved of great help in these old and helpless patients, and will certainly be of assistance in the routine work of treating constipation.

We also investigated the duodenal contents of a number of patients employing isacen. We usually had the patient take one tablet (0.005 Gm.) of isacen on retiring, and we examined the duodenal contents of the patient the next morning in the fasting condition. In some, neither isacen nor isatin could be detected by the foregoing reactions; in others, we succeeded in demonstrating the presence of isacen only.

In a number of patients who were on duodenal feeding, isacen was given directly through the duodenum. Some patients showed no symptoms and had a bowel movement daily, while a few complained of nausea and slight colicky pains in the abdomen. Anyway, when isacen is applied through the duodenum, more frequently undesired symptoms are encountered than when given by mouth. The reason for this is the larger amount of isacen reaching the duodenum at one particular time, while when administered by mouth, only very small fractions of the medicament reach the intestine at one time.

PHYSIOLOGIC EFFECTS OF SPERMATOXIN

IN RATS, RABBITS AND GUINEA-PIGS *

ROBERT M. OSLUND, M.S., Ph.D.
CHICAGO

One of the chief obstacles preventing definite location of the source of the testicular hormone has been the fact that the several types of tissue in the testis have been inseparable. Only a few authors have been bold enough to state that in their experiments only one type of tissue remained, the other tissues having degenerated. Always in addition to interstitial cells there have been present Sertoli cells and in most cases also spermatogonia. A few workers have claimed partial degeneration of Sertoli cells, but their evidence lacks conviction. As Whitehead [1] stated, only when we can definitely eliminate each type of tissue will the problem be solved.

In seeking a method of eliminating each type of tissue in the testis, it occurred to me to use the cytolysin or antibody production method. In this way, it was hoped that a specific antibody for the germ cells might be produced which would cause complete elimination of the germinal epithelium in treated animals. This specific antibody might conceivably destroy all the germ cell line and leave only Sertoli cells and interstitial cells. Furthermore, it seemed probable that such a cytolysin would also destroy the Sertoli cells because of their position in the seminiferous tubule and because of their otherwise close relationship to spermatogenesis.

The production of such antibodies for sperm has been reported by many workers. Metchnikoff [2] and Landsteiner [3] introduced this field of investigation in 1899. Since then it has been reported on by a number of experimenters. I have found no reports of negative findings; i. e., that a spermatoxin is not formed.

Various criteria have been used as proof of the formation of such spermatoxin. Among these are immobility and agglutination of sperm by serum from immunized animals, delayed pregnancy in immunized females, and injury of the testes in animals injected with their own sperm or sperm from other species of animals.

I have been unable to obtain any evidence of a physiologic reaction. Several series of experiments testing this point have been performed, the fertility of both male and female animals and the condition of the testes being used as criteria. These have been adopted as physiologic tests, leaving the agglutination reaction as a distinct serologic problem. This course has been taken because it is my belief that a serologic or

immunization reaction may be set up without in any way interfering with the production of spermatozoa or with the fertility of ova.

Albino rats, guinea-pigs and rabbits have been used in these experiments. The work was started on rats because of their fecundity, and because of the fact that they are well adjusted to laboratory confinement. They do not, however, serve well for the production of antibodies, and it was thought best to extend the series by using guinea-pigs and rabbits. The latter animal has been found adapted to this work and has also been used in experiments on spermatoxin formation. The results are presented in several series according to their nature, and the accompanying tables summarize each group.

REPORT OF EXPERIMENTS

Twelve male rats were injected with a suspension of sperm in saline solution. This was obtained by cutting testes into small pieces and shaking in sterile saline solution. One testis finely minced and shaken in 5 cc. of saline solution was used as a standard suspension. Sperm from several species of animals has given the same results, but for the sake of uniformity only those experiments in which rat sperm has been injected into rats, guinea-pig sperm into guinea-pigs and rabbit sperm into rabbits are reported in this paper. Each rat was injected (intraperitoneally) from one to five times, 1 cc. of sperm fluid to each injection being used. The number of days between injections varied, as will be seen in table 1. The condition of the testes was the only criterion used in this series as a test for results. Testes were removed from these animals at from seven days to four months after the last injection. The testes were then prepared for microscopic study in the usual manner.[4] In experiments 4, 6 and 10 of this series, degeneration of seminiferous tissue was found. In experiment 4, both testes were removed fourteen days after the last injection. The degree of degeneration is not the same in each testis, and both showed many tubules which appear perfectly normal. In experiment 10, one testis, removed fourteen days after the last injection, was normal. No sign of degeneration was found in it. The other testis, removed thirty days after the last injection, had some degenerated seminiferous tubules, while the remaining were normal. In experiments 4 and 6, the degeneration was found within fourteen days, while in experiment 10 it was found at thirty days, though not at fourteen days. All animals in this series were well advanced in age. At such times it was not uncommon to find them with the testes retracted into the abdominal cavity. Testes are very sensitive to conditions such as malnutrition, anaphylatic shock and even unfavorable environment. The degree of degeneration found in these experiments and the irregularity of their appearance, as in experiment 10, indicates such a response.

Table 1.—*Results of Experiments in Male Rats Injected with Sperm*

Experiment	Dates of 1 Cc. Injections	Time Between Last Injection and Removal of Testis	Condition of Testes
S 2.......	1-6-20-30-44	Right....14 days	Normal
		Left......14 days	Normal
S 3.......	1-6-20-30	Right.... 2 months	Normal
		Left...... 4 months	Normal
S 4.......	1-6-20-30-44	Right....14 days	Some tubules degenerated; other tubules normal
		Left......14 days	Disorder in some tubules; other tubules normal
S 5.......	1-6-17-27	Right.... 1 month	Normal
		Left...... 1 month	Normal
S 6.......	1-19-29	Right.... 9 days	No spermatozoa but spermatids; extensive degeneration in some tubules
		Left...... 9 days	Same as right testis
S 7.......	1-17-27	Right.... 4 months	Normal
		Left...... 4 months	Normal
S 8.......	1-4-8	Right....14 days	Normal
		Left......14 days	Normal
S 9.......	1-7-13	Right.... 1 month	Normal
		Left...... 2 months	Normal
S 10.......	1-7-13	Right....14 days	Normal
		Left...... 1 month	Some tubules show degeneration; other tubules normal
S 11.......	1-7-13	Right.... 7 days	Normal
		Left...... 1 month	Normal
S 12.......	1-4-8	Right....14 days	Normal
		Left...... 1 month	Normal

		Left...... 1 month	Normal

Table 2.—*Results of Experiments in Male Guinea-Pigs Injected with Sperms*

Experiment	Dates of 15 Cc. Injections	Time Between Last Injection and Testis Removal	Condition of Testis
S 43........................	1-4-8	One week	Normal
S 44........................	1-4-8	Two weeks	Normal
S 45........................	1-4-8	Three weeks	Normal
S 46........................	1-4-8	Four weeks	Some denegeration
S 47........................	1-4-8	Four weeks	Normal
S 48........................	1-4-8	Five weeks	Some degeneration

Spermatogenesis appeared normal in nine of the twelve experiments, though some of the testes seemed slightly flabby before fixation. As most of the testes were normal, it seems reasonable to suppose that this is the natural course of events in such experiments.

In a second series of experiments, rabbits were used instead of rats. Two males were each injected three times at three day intervals with 1 cc. of rabbit sperm suspension. They were killed three weeks and one month after the last injection. In both animals the testes were normal.

In a third series, six guinea-pigs were used. Each animal was injected three times at three and four day intervals with 1.5 cc. of guinea-pig sperm suspension. Testes were removed from these animals at periods of from one to five weeks after the last injection (table 2).

In each of four experiments there was full spermatogenesis, and the testes appeared normal. These animals had been used for bleeding purposes before these experiments were undertaken, and control testes were also degenerated.

Guyer[5] reported several of these experiments in which spermatozoa taken from rabbits that had been injected with their own sperm were used for agglutination tests. Certainly in these experiments spermatogenesis had continued, if he obtained sperm from them for later use. In other experiments, as in experiment 1, the rabbit, after five injections of immunized fowl serum, fertilized a female three days after the last injection. Later matings were unsuccessful, though the testes presented normal histologic pictures. In these experiments the degenerative process should have started at once, since the developed antibody (immune serum) was injected. Professor Guyer suggests the possibility that the effect on spermatogenesis might be due simply to the general lowering of the animals' vitality; he thinks, however, that it is a spermatoxic effect.

---

[4] Compare, for example, Oslund, R. M.: Am. J. Physiol. **70**: 112 (Sept.) 1924.

[5] Guyer, M. F.: J. Exper. Zool. **35**: 207, 1922.

McCartney[6] reports that in adult male rats injection of rat spermatozoa or extract of testis results in the destruction of spermatoza and in some cases in atrophy of the testis. He presents six experiments. Two of these rats became sick and should not be included. In one rat the testis at first became enlarged and later atrophied. They contained about half the normal number of spermatoza, and these were immotile. Two other rats showed enlargement of the testes for the first two weeks, but within a month had returned to normal size. "On examination seven weeks after injection, the testes appeared normal, although they did not contain as large a number of spermatozoa as normally. These were motile." The sixth was not affected by the injection of testis extract. In this series, therefore, are found three "normal" rats and one with atrophied testes which had about half the normal number of spermatozoa. These were immotile.

Kennedy[7] reported degenerative changes in the testes of guinea-pigs into which had been injected spermatozoa. He reported that the effects were more pronounced when the animals' own sperm was used for the injection. In Kennedy's experiments the results were not constant. The degenerative changes were found in some of the testes, while the others were normal.

In each of the series by Guyer, McCartney and Kennedy are found experiments in which spermatogenesis is apparently undisturbed, and the animals were fertile. These results are similar to those I obtained and indicate that degeneration of germinal epithelium is not necessarily a consequence of such injections of spermatozoa.

It was reported by each of the workers cited above that females injected with sperm became sterilized, because of the formation within them of an antibody against sperm. Other series of experiments were performed to test this point. In each of these series, the same standard of sperm has been used as in the male experiments.

Table 3.—*Results of Experiments in Females Injected and Then Mated*

Experiment	Dates of 1 Cc. Injections	Number of Young	Days After Last Injections
50	1-4-7	9	22
51	1-4-7	12	26
52	1-4-7	7	28
53	1-4-7	13	35
54	1-4-7	10	39

In one series five female rats (all virgins, 4 months old) were each injected with 1 cc. of sperm at three day intervals. They were then each placed with a male. Good litters were raised from each mating. Results in brief are given in table 3. Gestation varies from twenty-one to twenty-eight days, and copulation takes place when the female comes in heat. Since the maximum time between the date of mating and the birth of the young was thirty-nine days, in each case the first copulation must have been successful.

Another series of experiments was made to determine the possibility of producing sterility in female rats by injecting sperm into them. In this series six female rats were first mated, and then the injections were begun. Each rat received two or three injections of 1 cc. of sperm at three day intervals. Each animal was then placed in a separate brood cage. Results are tabulated in table 4. Rats 33, 35 and 36 each gave birth to good litters of young within two weeks of the last injection. Rats 31, 32 and 34 did not give birth to young from this mating. Rats 31, 32 and 33 were again mated about thirty days later, and each gave birth to good litters. The maximum time from the last injection to birth of the second litter of young was seventy days. Forty-nine days elapsed before pregnancy took place, but during that time this rat was isolated and nursing young. She received the male at the next heat period, and this copulation was successful.

Table 4.—*Results of Experiments with Females Mated and Then Injected*

Experiment	Dates of 1 Cc. Injections	Number of Young	Days After Last Injection	Number of Young from Second Mating	Time After Last Injection
31	1-4-7	0	..	8	62 days
32	1-4-7	0	..	8	48 days
33	1-4	10	14	10	70 days
34	1-4-7	0	..	Not mated	....
35	1-4-7	9	11	Not mated	....
36	1-4-7	10	11	Not mated	....

In these two series of experiments, injection of sperm into female rats has not prevented pregnancy. Nor has it in any case delayed pregnancy. It has caused abortion. Successful copulations took place soon after the last injection—in one case on the following day.

It was thought possible that a spermatoxin may have been developed in the female, and this affected the embryos after passing through the placenta. First matings of both male and female offspring proved successful in every case. The young did not suffer in fertility or in any other demonstrable way from the injection of sperm into their mothers before or during pregnancy.

In these two series of experiments in which females were injected with sperm, pregnancies took place from the first copulations following the last injection. In no case was copulation unsuccessful. In three experiments, rats that were injected during pregnancy gave birth to full litters of young. The young were fertile in all cases and were used as breeding stock.

Savini[8] made from five to six subcutaneous or intraperitoneal injections of sperm into fifty-seven female rabbits and guinea-pigs one week apart. Seven days after the last injection, these females were allowed contact with males. They were placed together for from ten to fifteen days. Copulations appear not to have been noted. No young resulted from the first contacts, but in many cases conception took place on a second contact of five days only. This is not altogether uncommon for normal breeding stock of rabbits, though some conceptions would be expected from the first contacts. If the contacts happened to occur between the heat periods, the same would be true for the guinea-pigs. The period of immunity was strikingly short, if it existed in Savini's experiments, in that young were produced from the second contacts. He also states that no injurious effects were noted in mice which he injected with sperm. Venema[9] reported two experiments in which he injected a saline suspension of testis into female rabbits. The suspension was kept in an icebox three hours and then before injection was strained through cloth. Pregnancy did not follow, although the females were kept with the males for some time. This was probably part of the difficulty. Pregnancies seldom result from continued contacts in normal rabbits. Dittler[10] injected female rabbits with fresh sperm at intervals of from one to eight days. After two injections of 2.5 cc. four days apart sterility lasted four weeks. Since the heat period in rabbits occurs about every thirty or thirty-two days, it appears that pregnancy took place at the next copulation. He further states that though no pregnancies resulted after such injections, conception occurred later. After injection with large doses of human sperm his animals always appeared entirely normal. McCartney[11] reported a series of spermatoxin experiments on female rats. From his table,[12] it appears that injections of sperm or testis extract delay pregnancy. Some of his animals, especially those injected with testis extract and human semen, produced young from the first possible matings, as litters were cast in four weeks. His report is based on seventy-nine breeding tests, but so many deaths were reported that the condition of his animals may well be questioned. He reports, however, that all his controls were fertile. All tested young from injected females proved perfectly normal in his series. In the first paper he also reported a series of six experiments on chickens. From them he concludes that subcutaneous injection of rooster sperm suspension into egg-laying hens does not influence the rate of egg production, but renders the egg infertile for a period of from twelve to sixty-seven days. Kennedy[7] stated that female guinea-pigs were made sterile by injecting spermatozoa into them.

COMMENT

In all the experiments reviewed, pregnancies have resulted from some of the early matings after injections of sperm or sperm extract. As contended by the writers, the pregnancies have generally been delayed, but only to the next period of heat in the great majority of experiments. If we accept experiments as recorded and interpreted, it appears that an antibody (a spermatoxin) has been developed in the female, which in most experiments has not lasted more than thirty days. Such a fact is conceivable but highly improbable. The present status of experiments indicates that toxins or antibodies remain active for a longer peroid of time.

Immunity reactions are limited in their influence in the body. Immunity to typhoid does not appear to extend into the digestive tract, nor do the gonococci antibodies affect gonococci in the urethra or vas deferens. An antibody built against sperm would not injure the chemical constituents used in the construction or nourishment of sperm, but would be toxic for the built up products and slightly toxic for the closely related cells. A spermatoxin in the blood of a male rat, rabbit or guinea-pig would have to wield its toxic influence on sperm through the walls of the seminiferous tubules. It is unlikely that spermatozoa in the seminiferous tubules, in the epididymis or in the vas deferens would be injured by a spermatoxin found in the blood of that animal.

The situation in the female is analogous. The ovum is quite secure against any antibody that might be present in the maternal blood. The vaginal and uterine secretions might, but very probably would not, contain these antibodies or spermatoxin. McCartney,[13] however, reports agglutination tests in which such fluids were used showing probable reactions. Functionally, these animals prove to be normal.

There is little reason to doubt that a sperm antibody is produced in animals into which sperm of another species has been injected.[14] There is reason to doubt that a sperm antibody has been built up in the blood of the animals into which their own sperm or sperm suspension has been injected.[15] It is not a foreign protein. In some experiments an autospermatoxin has supposedly been produced in the observed animals following such injections. With an antibody present in the blood of an injected animal, physiologic changes should follow were it not for the limited sphere of antibody activity. Physiologic reactions have been reported, but it is very probable that these antibodies either formed in the blood or injected into it are unable to attack spermatogenic cells in the genital organs.

Metalinikov and Strenikov[16] stated that when spermatoza are placed in the body tissues, a spermatoxin is produced, although the antigen may be implanted in the tissue as an entire testis graft. This seems quite reasonable from a general point of view. It is a foreign protein. But it may persist and grow as a part of the host bearing it. Whether or not there is formed an antibody against it in the blood of the bearer is beyond the point of this paper. Such an antibody, if present, has no effect on spermatogenesis in the case of the male, or on fertility in the case of females. Copulations of males bearing testis grafts have been successful in my cages, and Moore[17] has reported females bearing testis grafts giving birth to young. Such testis grafts usually contain only spermatogonia and some spermatocytes, but these cells should provide an antigen almost identical with spermatozoa.

In another series of experiments on guinea-pigs and rats, the vas deferens was resected. The testicular end was left open, so that the spermatic material formed in the testis flowed into the peritoneal cavity. In these experiments an antigen has been supplied constantly. The testes of these animlas were normal when removed at from one week to six months after resection of the vas.

SUMMARY

It therefore appears that spermatoxins developed in the blood of the male animal have no effect on spermatogenesis or on mature sperm in the genital tract. Temporary aspermatogenesis found in some experiments is probably a consequence of general body reaction, to which testes are very sensitive, and not a specific reaction. The aspermatogenesis reported by various writers is too irregular in its appearance to be the result of specific antibody built up by regular procedure. It also appears quite probable that spermatoxins developed in the blood of the female animal have no effect on the natural response of its ova to sperm.

General bodily reactions, especially the resulting anaphylaxis, cause abortion of ova and often of embryos, if the animals are pregnant. The delay of pregnancy occasionally found appears to be very short in duration and is probably caused by physical disturbances of the body rather than by antibody reactions. Some of the delayed pregnancies reported in the literature appear to have been due to breeding conditions.

IMPORTANCE TO THE PRACTICING OPHTHALMOLOGIST OF CONTRIBUTING TO LITERATURE *

ARNOLD KNAPP, M.D.
NEW YORK

To make a satisfactory contribution to literature, it is necessary first of all to select a subject, and then to be familiar with the literature pertinent to that subject.

Some knowledge of literature is in fact a necessary qualification, and this is not as difficult as it may seem, for our fundamental knowledge of any subject can be learned from textbooks. They contain the accumulated knowledge of previous observers which time has shown to be correct. Our knowledge grows through the addition of new observations, which in turn must be substantiated before they are adopted and admitted to the textbook. During this probationary period, which is necessarily often quite long, the observations must be made available by appearing in the current journals. A knowledge of these observations is necessary to keep abreast of one's subject. Their study creates new interest in our work, which from repetition frequently becomes monotonous, and this result is never more true than in our work as specialists. Our minds become prepared for new observations and new points of view, and we enlarge our points of contact with those whom we are otherwise not likely to meet. The publication of a new observation thus brings about an active exchange of opinion, our literature becomes more virile, and greater progress is made toward our common goal, the elucidation of truth. It is stated that the dignity of any branch of learning is directly proportionate to the excellence of its literature. What, then, can be more important for any of us than to have participated even in the humblest way, in the development of ophthalmology?

The desire to contribute to literature makes for a more careful examination of our observations. Did not Francis Bacon say many years ago, "Reading maketh a full man, conference a ready man, and writing an exact man"?

The genius of ophthalmology lies in fine distinctions. Our problems, owing to the delicacy of the eye, are characterized by their exactness, so that there must be a willingness to make fine distinctions, which in turn require exact thinking, and thus induce sound action.

There is no better way to find out omissions in our work than in attempting to write about it. The necessary thinking over our findings, so as to come to a logical and satisfactory conclusion, is of the greatest value. The gaps in our knowledge and reasoning can be shown up better in writing than by any other means.

It is frequently stated by the new observer that he finds nothing worth while to write about. This I think means that he has not sufficiently studied the subject. Since the humblest observations may be the basis for a satisfactory report, it is not necessary to wait for divine inspiration to publish an epoch-making discovery. Remember what Ruskin said: "It is no man's business whether he has genius or not; work he must, whatever he is, but quietly and steadily, and the natural and enforced results of such work will be always the things that God meant him to do, and will be his best."

All too frequently writing is postponed and the time for the development of this important habit is passed by, until difficulties increase, and become unsurmountable.

Allbutt says that "inspiration for advance in medicine must be derived from observation of patients." Therefore we should examine our cases thoroughly, make very full notes, and not trust to the memory. The value of a simple but carefully completed clinical contribution should *not* be underestimated; while it may not of itself solve a problem, it may help the correct interpretation of the next case. There is no more helpful statement than Paget's that "practice is full of opportunities for science. Clinical science is as much a science as any other branch of biology. It is the best means of increasing our knowledge of disease."

So we should not hesitate or postpone, but make a beginning in writing; an observation should be written up while it is fresh in one's mind and full of interest. Remember Faraday's secret, which he summed up in the words "Work, finish, publish."

THE TREATMENT OF THROMBO-ANGIITIS OBLITERANS

BY INTRAVENOUS INJECTION OF HYPERTONIC SALT SOLUTION: PRELIMINARY REPORT *

SAMUEL SILBERT, M.D.
NEW YORK

Nothing very positive can be stated as regards the etiology of the peculiar disease that was studied by Buerger and called by him thrombo-angiitis obliterans, and no satisfactory explanation has as yet been given for the peculiar distribution of the disease. It is our belief that some hereditary transmitted defect, probably sex-linked in character, plays an important part in its causation. Whether the abnormality is primarily one of the blood, of the blood vessels, of the sympathetic nervous system or of the glands of internal secretion, is yet to be determined. There are some facts that point to a possible involvement of any one of these four systems. The discovery of the real nature of this disease is of great importance if a rational therapy is ever to be evolved, and studies along these lines are being carried out in the special clinic established for the treatment of this group of patients, in the outpatient department of Mount Sinai Hospital.

Spontaneous remissions are frequent, and therefore proof of successful treatment is difficult to establish. The pain will often stop of itself; less frequently the ulcers heal without treatment, and occasionally the formation of collateral vascular channels or the reopening of occluded vessels will occur spontaneously. If it were possible to determine that in all the patients amputation of the affected limb is inevitable sooner or later, the ability to save the extremities of these patients would be satisfactory and conclusive evidence of the success of a form of treatment. A review of the clinical histories of the large number of patients who have been studied and treated in Mount Sinai Hospital during the last fifteen years shows definitely that amputation of one limb was performed within a period of five years from the onset of symptoms in a large majority of cases. If, therefore, the greater number of patients who have been subjected to a particular form of treatment did not require amputation within a period of five years from the beginning of treatment, the value of the therapeutic method used would be indubitable.

---

* From the Surgical Service of Mount Sinai Hospital.

* In view of the fact that a better method is now available, the injection of the posterior tibial nerve with alcohol, as advocated in 1922, has been completely abandoned and should not be used in the treatment of these cases

For over three years I have employed frequently repeated intravenous injections of hypertonic salt solution as a method of treatment of thrombo-angiitis obliterans, and the results appear of sufficient value to justify a preliminary report. Although two or three more years will have to elapse before the measure of success in preserving the extremities of the first fifty patients treated can be reported on, the beneficial results appear so definite that attention should be called to a simple, although not entirely original, method of treatment.

The administration of fluids to patients with thrombo-angiitis obliterans, whether subcutaneously, as first suggested by Koga in 1913, intravenously, or by duodenal tube, as carried out by later writers, has been followed by improvement in some of the patients. Intravenous injections of hypertonic citrate solution have been used with benefit, and the good results were believed to be due to the citrate itself. I have employed hypertonic sodium chloride solution for the injections, and only in this respect is there any originality in the method of treatment. Sodium chloride was selected for the hypertonic solution because it is the salt to which the body is accustomed, and because 15 Gm. can be administered without danger of toxicity. The solution is prepared in freshly distilled water, filtered, and immediately sterilized. At the present time, 5 per cent sodium chloride is used, 150 cc. for the first injection and 300 cc. for all subsequent injections. The injections are at first given three times a week, later, twice a week, and the length of intervals further increased as the patient improves. The injection is given into a superficial vein in the usual manner by the gravity method; the fluid is allowed to run into the vein slowly during ten minutes, and the patient is kept flat on his back during this period. If care is taken, the superficial veins will not be injured or become thrombosed, so that the same vein can be punctured again and again. If the solution has been properly made, chills or fever should rarely, if ever, follow the injection. I have given or supervised the giving of more than 2,500 injections, without any serious accident or reaction.

No other means of treatment has been regularly employed in the cases that we have treated. A certain number of patients received potassium iodide in the usual doses; some at their own suggestions continued baking and hot baths, and in two, local stimulative treatment of an ulcer with the roentgen ray seemed of value. All patients were urged to drink large quantities of water. The patients who continue to smoke frequently do not improve, and although we do not know the explanation of this phenomenon we have strictly forbidden the use of tobacco. It is exceedingly difficult to make the patients stop smoking, and it is only by repeated warnings and constant admonition that it can be accomplished.

During the injection, the blood volume is increased and the patients often state that they feel warm; the face becomes flushed and the superficial veins engorged. They often complain of thirst. The excretion of the 15 Gm. of sodium chloride injected takes place through the urine within forty-eight hours—approximately two thirds of the salt being excreted the first day, and one third the second day. The administration of hypertonic salt solution produces a certain amount of blood destruction. A slight amount of urobilin may appear in the urine, and a reduction in hemoglobin and red blood cell count will occur. As the majority of patients with thrombo-angiitis obliterans have a high hemoglobin and red cell count, a slight blood destruction is of no serious consequence. No symptoms of anemia have ever been produced even in patients who have been treated for a very long time; but if a mild anemia should occur, the injections should be stopped for a time, or diminished. No injury to the heart or to the kidneys has ever been seen, in spite of prolonged treatment in many cases. It is advisable to examine the urine and to repeat the blood count once a month to follow any changes that may occur. On theoretical grounds, it would seem that the repeated increase in the blood volume, necessarily stretching the vascular system, is responsible for the improved circulation and the development of the collateral blood supply that results. Another possible factor is the dilution of the blood with resulting decrease of viscosity.

Since February, 1923, more than 2,500 injections of hypertonic salt solution have been given to sixty-six patients. The accompanying table gives the results.

Results of Injections of Hypertonic Salt Solution

Improved	46
Unimproved or too early to judge result	14
Amputations necessary	6
Total	66

Improvement may be noted immediately, but more frequently not until at least a few weeks have elapsed. In many cases treatment must be continued for several months before definite evidence of improvement appears. The first subjective evidences of benefit are usually the increase of warmth in the extremities, with a diminution of pain. Objectively, the increase in the temperature of the extremity and the growth of new nails are first seen, then healing of an ulcer, if one is present, and finally the development of pulsation in previously occluded or collateral vessels. In addition, a gain of weight and improvement in the patient's general health was also noted. The healing of ulcers has been the usual rule in nearly all of the cases listed as "improved," although in a few cases from eight to ten months of treatment were necessary. In about one third of the patients who have been treated for over a year, a return of pulsation in the previously obliterated or in a collateral vessel has been found. When a patient has been restored to good health, the intervals between treatments have been lengthened to once a month and less. No patient has been discharged as cured, as it was felt that this would be unsafe; but no patients who have been kept under observation in this way have had a recurrence of symptoms. The best general evidence of the value of the treatment will be seen from the statement that the majority of the patients, many of whom have been unable to work from periods of from six months to three years, were able to return to work and were restored to economic usefulness. The treatment must sometimes be continued for months.

In some instances the treatment is without results, and some of the failures have been in advanced cases in which gangrene had already set in. Even in these patients, however, the treatment has sometimes proved of value. In the last four of these patients, treatment for at least two months had been given before amputation became imperative. In all of these, amputation at the middle of the leg was performed and a successful result was obtained. It scarcely needs to be stated that when amputation becomes inevitable it is important to give the patient a stump below the knee if at all possible. While amputations below the knee have occasionally been successful in cases of thrombo-angiitis obliterans in which treatment has not been given, this is certainly the exception rather than the rule, as will be apparent to any one who sees a large number of these crippled men. Four consecutive successful amputations at the middle of the leg are not many, and it is far from my desire to claim that all such amputations will meet with equal success. The fact is recorded as possible evidence of the value of the saline treatment administered to these patients, but only further experience can demonstrate whether this was not merely a coincidence.

SUMMARY AND CONCLUSIONS

1. Repeated intravenous injections of hypertonic salt solution have been used in the treatment of sixty-six cases of thrombo-angiitis obliterans.
2. Improvements have resulted in the majority of patients, those noted being cessation of pain, increased temperature of the extremity, growth of the nails, healing of ulcers, and reopening of obliterated vessels.
3. No dangerous reactions or untoward results of any kind have been noted in more than 2,500 injections.
4. Four consecutive successful amputations below the knee have been done in four advanced cases after preliminary saline treatment.
5. If begun before the disease is too far advanced, treatment of thrombo-angiitis obliterans by repeated injections of hypertonic sodium chloride solution will check the progress of the disease and will restore the patients to health and usefulness in the majority of instances.

CALCIUM ABSORPTION FROM THE INTESTINAL TRACT IN HUMAN SUBJECTS

AN EXPERIMENTAL STUDY *

BERNARD S. KAHN, A.B.
AND
JOSEPH H. ROE, Ph.D.
With the Cooperation of A. S. Finkelstein
WASHINGTON, D. C.

There are numerous reports in the literature of the therapeutic value of calcium salts when given by mouth, more particularly in such conditions as the hyperesthesias and hypersusceptibilities; but their authors have never shown any convincing proof in the way of laboratory findings. Some assert that they have obtained slight elevations in the blood calcium level, but the blood changes reported were very small, and in no case have the blood analyses shown a variation great enough to indicate definitely that they were not due to experimental error.

The absorption of calcium from the intestinal tract has been the subject of much discussion and the objective of a vast amount of research. Many investigators have denied that calcium is stored in the tissues or even absorbed from the intestinal tract. A great number of experiments have been reported in which animals were given large amounts of calcium salts orally and did not show retention of calcium in the tissues, or a rise in the blood calcium level. Meigs, Blatherwick and Carey[1] have reported that there was a very slight increase in the plasma calcium after feeding calcium chloride to cattle, but the difference was within the limits of experimental error. Denis and Corley[2] found no elevation of serum calcium in rabbits fed daily doses of calcium chloride and calcium lactate, and no higher calcium content of the tissues than that shown in control animals. Halverson, Mohler and Bergein,[3] and Clark,[4] have published work showing no increase in the calcium content of blood serum in animals given a calcium rich diet, or calcium with their food. Denis and Minot[5] have reported that the blood calcium of normal human subjects was not elevated by the daily ingestion of 6 Gm. of calcium lactate for a period of ten days. Salvesen, Hastings and McIntosh[6] found no increase in blood calcium in men given 10 Gm. of calcium lactate and 13.5 and 15 Gm. of calcium chloride daily for periods of from four to nine days; also in dogs, given from 15 to 20 Gm. of calcium chloride and calcium lactate daily for from two to four days, except a 20 per cent increase in the serum of one dog.

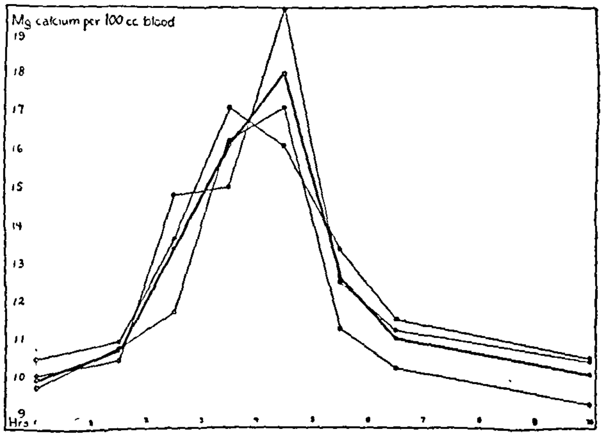

Chart 1.—Hourly blood calcium concentration in three subjects given 20 Gm. of calcium lactate by mouth: The heavier line indicates the average of the three curves.

A perusal of the foregoing papers reveals that single isolated calcium estimations were made in every case and that the relationship of blood calcium concentration to time of ingestion was not considered, the analyses being performed usually twenty-four hours, or several days, after the last calcium ingestion. This probably accounts for a failure to find any change in the blood calcium concentration by these investigators.

Recently Hjort,[7] examining the blood hourly or at two hour intervals, has shown that the normal blood calcium is elevated in dogs by giving calcium salts orally. When calcium salts were given in amounts equivalent to 0.2727 Gm. of the oxide per kilogram of body weight, this author found the following elevations of the normal serum calcium: with calcium lactate, from 17.4 to 48.7 per cent; with calcium chloride, 32.1

per cent; with calcium glycerophosphate, 8.26 and 9.8 per cent; with calcium carbonate, 7.8 per cent.

Because of the interest in the subject of calcium absorption, and in order to obtain evidence relating to the therapeutic administration of calcium salts, the following experiments on human subjects were carried out. The method used for the estimation of calcium was the colorimetric procedure, which we[8] developed, and with which we have had considerable experience. Most of the determinations on any one subject were carried out simultaneously and read against the same standard, and they therefore represent accurate relationships. The subjects were medical students showing no clinical evidences of disturbed calcium metabolism.

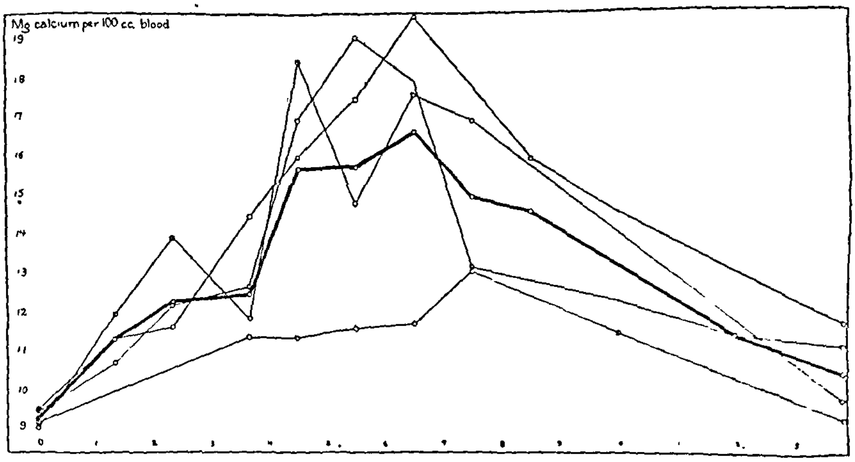

Chart 2.—Hourly blood calcium concentration in four subjects given 5 Gm of calcium lactate by mouth: The heavier line indicates the average of the four curves

REPORT OF EXPERIMENTS

Experiment 1.—This was a repetition of the work of other authors. Two subjects were used. Blood calcium estimations were made on three successive days on samples of blood drawn before breakfast, these values being obtained to establish the individual normals as controls. Five grams of calcium lactate was then given orally on each of the five days following the control period. Blood was drawn on the sixth day before breakfast and analyzed for calcium. There was no increase in the blood calcium concentration, a result that coincided with the observations of Denis and Minot.[5] These findings are summarized in table 1.

Table 1.—*Summary of Blood Calcium Estimations in Experiment 1*

Test	Subject A, Mg. of Calcium per 100 Cc. of Blood	Subject B, Mg. of Calcium per 100 Cc. of Blood
Normal, first day	9.42	9.78
Normal, second day	9.47	9.82
Normal, third day	9.43	9.78
Average normal	9.44	9.79
After 5 Gm. a day oral administration of calcium lactate	9.47	9.75

Experiment 2.—Three subjects were given 20 Gm. of calcium lactate orally in approximately 300 cc. of water. A control value was obtained previous to ingestion, and estimations were made on samples of blood drawn hourly for seven hours. The results are shown in chart 1. The curves show maximum elevations of the normal blood calcium of 64, 76 and 102 per cent between the third and fifth hours following ingestion. The hourly average curve for the three subjects shows a maximum elevation of 81 per cent between the fourth and fifth hours after ingestion, and returns to normal by the tenth hour.

Experiment 3.—The normal blood calcium was obtained on four subjects, who were then given 5 Gm. of calcium lactate by mouth in 300 cc. of water. Calcium estimations were performed on samples of blood taken hourly for eight hours, and then on samples taken ten, fourteen and twenty-four hours after ingestion. The results are shown in chart 2. The curves are less regular than in the 20 Gm. ingestion experiment. Maximum elevations of 43, 104, 105 and 108 per cent were obtained between the fourth and the seventh hours. The hourly average curve reaches a maximum elevation of 80 per cent above normal between the sixth and seventh hours, and remains elevated much longer in this experiment than in experiment 2, returning to normal approximately fourteen hours after ingestion of the calcium salt.

Experiment 4.—The normal blood calcium was determined for three subjects, after which they were given 2 Gm. doses of calcium lactate. Samples of blood were drawn four hours after ingestion, no food being taken in the interim, and analyzed for calcium. After the fourth hour, blood was drawn and analyzed for five consecutive hours, and, since at the end of this time the blood calcium concentration of all the subjects had returned to normal, no further samples were taken. The results are shown in chart 3. The curves are smooth, and show striking similarity. Maximum elevations of 43, 53 and 54 per cent were obtained at approximately the sixth hour after ingestion. The hourly average curve exhibits a maximal elevation of 49 per cent at the sixth hour, and returns to normal eight hours after ingestion.

COMMENT

These experiments show that calcium is absorbed from the intestinal tract just like any other diffusible substance. There is a rise in the blood calcium concentration following the ingestion of calcium salts, which varies according to the size of the dose, but is not strictly proportional to the amount taken. The average curves for the 2, 5 and 20 Gm. ingestion experiments (chart 4) show that the first appearance of calcium in the blood is favored by large dosage, the peak of the curves occurring in the order of size of dosage in each experiment. The return of the blood calcium concentration to normal is not proportional to dosage, however, which is a very important point, therapeutically. The 5 Gm. administration maintained an elevation above 12 mg. of blood calcium per hundred cubic centimeters for nine hours, while the 20 Gm. dose maintained the

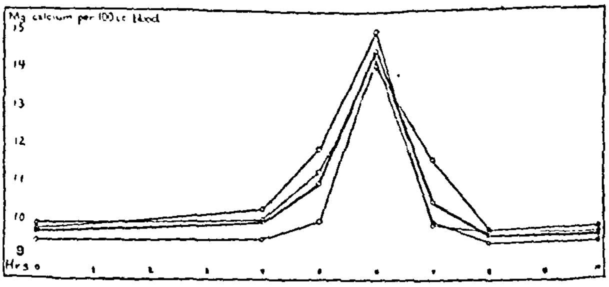

Chart 3.—Hourly blood calcium concentration in three subjects given 2 Gm. of calcium lactate by mouth: The heavier line indicates the average of the three curves.

---

[8] Roe, J. H., and Kahn, B. S.: J. Biol. Chem. 67: 585 (March) 1926.

same elevation less than four hours, and the 2 Gm. dosage about one and one-half hours. The only explanation we suggest for the more rapid return of the blood calcium concentration to normal in the instance of the 20 Gm. experiments is possibly an increased irritation of the intestinal mucosa by the larger amount. These findings show that optimal absorption is determined by two opposing factors, mass action of the dose, and, possibly, irritant action of the salt, and that optimal absorption will be the resultant of these two opposing influences. Our experiments indicate that 5 Gm. of calcium lactate represents approximately the optimal dose when this salt is given by mouth. Below this amount there is insufficient mass action, and above this quantity some unknown influence, possibly irritation of the intestinal mucosa, depresses absorption.

SUMMARY

Calcium lactate administered orally to ten human subjects showed elevations of the blood calcium level as follows: Twenty gram doses gave an average maximum elevation of 81 per cent between the fourth and fifth hours following administration, and a sustained elevation above normal for approximately four hours. Five gram doses gave an average maximum elevation of 80 per cent between the sixth and seventh hours following ingestion, and maintained an elevation above normal for approximately nine hours. Two grams gave an average maximum elevation of 41 per cent at the sixth hour following ingestion and a sustained elevation above normal for one and one-half hours. These findings are in disagreement with the work of many investigators, who have asserted that the blood calcium concentration cannot be increased by the oral administration of calcium salts, and they confirm the work of Hjort,[7] who found definite elevations of the blood calcium in dogs given calcium salts by mouth. Five grams appears to be the dosage of calcium lactate that will give optimal results therapeutically.

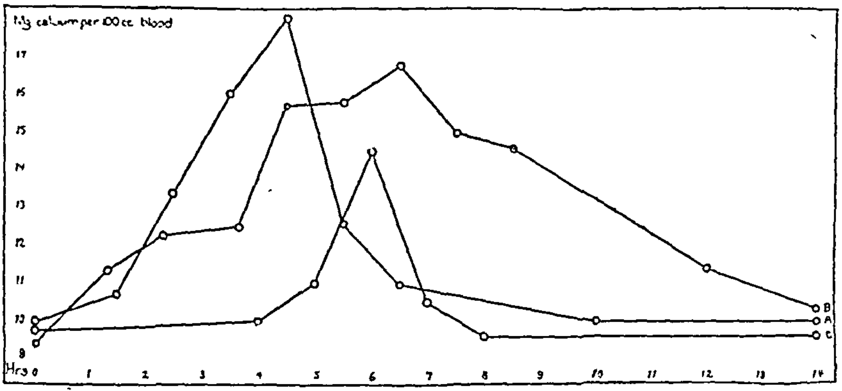

Chart 4.—Average curves for the blood calcium concentration in the three ingestion experiments, drawn on the same scale: *A*, 20 Gm. average curve; *B*, 5 Gm. average curve; *C*, 2 Gm average curve.

Source of Epinephrine.—Epinephrine is probably manufactured as a by-product of tyrosine, as is suggested by the presence of the oxyphenyl group in the chemical composition of the hormone. Tyrosine is a by-product of protein catabolism. If there is not sufficient ingestion of protein to allow of tyrosine and amino-acid derivatives being produced, the suprarenal bodies have not the materials from which to make epinephrine, except from their "tissue protein."—Dickson, Wanless: Endocrine Basis of Pernicious Vomiting in Pregnancy, *Practitioner*, May, 1926.

THE CAUTERY TREATMENT OF CHRONIC ENDOCERVICITIS

CARL HENRY DAVIS, M.D.
MILWAUKEE

Chronic endocervicitis, with or without erosion, is a very common condition. It is especially frequent among married women who have had one or more pregnancies, but may be found at times in patients with unruptured hymen. It is worthy of note that McGrath[1] found cervical disease in 38 per cent of the single women and 80 per cent of the married women in a series of 1,000 consecutive patients at the Cornell clinic who had a retrodisplacement of the uterus.

Chronic endocervicitis is always due to the presence of bacteria even though trauma, whether chemical or mechanical, may have acted as a predisposing cause. Microscopic studies from different portions of the cervix indicate that the glands near the external os are commonly diseased, while those near the internal os may appear normal. In the more recent cases, it is probable that the glands near the internal os need not be considered in the treatment. Winter,[2] in 1888, demonstrated that the endometrium of the uterus is normally free from bacteria, and this was confirmed by Curtis,[3] in 1918. Stroganoff[4] and Menge,[5] in 1895, working independently, found that bacteria are not normally present above the external os. Curtis,[6] in his last paper, states that his bacteriologic studies indicate that approximately 30 per cent of all patients with chronic purulent leukorrhea are carriers of virulent streptococci. He believes that while these organisms may account for spontaneous postpartum and postoperative infections, they should not be overemphasized as chronic foci capable of causing arthritis and other serious systemic disturbances. Laura Moench,[7] on the other hand, working with Rosenow at the Mayo Clinic, has demonstrated that streptococci grown from the chronically infected cervical glands of patients suffering from arthritis are culturally identical with the anaerobic streptococci grown from other foci of infection in these patients, and that experimentally they produce joint lesions in rabbits.

Cervical erosions are a frequent complication of chronic endocervicitis. They are an indication of the chronic irritation, and in the light of our present knowledge it seems probable that long continued irritation favors the development of cancer. A differential

diagnosis between early carcinoma and chronic endocervicitis with erosion may be impossible without a microscopic examination.

Every woman patient who complains of pelvic symptoms should have a speculum examination. Many physicians are overlooking more or less serious cervical disease through neglect of this simple procedure. Endocervicitis is frequently a factor in the production of one or more of the following complaints: dysmenorrhea, sterility, pelvic pain, dyspareunia, backache, menorrhagia or metrorrhagia, nervousness or general debility. When present, it should be cured as a part of the medical treatment.

The recognition that chronic endocervicitis is something of a menace to the patient's health has led to renewed efforts to cure it if possible without the surgical removal of the cervix. A high amputation removes the diseased tissue, but should be avoided if possible during the child-bearing period. The results following low amputation are frequently more or less unsatisfactory. The Sturmdorf conical excision of the cervical glands is undoubtedly the most satisfactory surgical treatment of this condition, but it means an operation and a hospital bill. Multiple scarification and the use of iodized phenol (carbolic acid) or local applications with silver nitrate, tincture of iodine and zinc sulphate require a large number of office visits, and the healing is often incomplete. The end-results with radium have not been very satisfactory, as the effects could not be limited to the cervical mucosa, and the bacteria were not destroyed.

Heat in various forms has been used successfully in the treatment of endocervicitis. Hunner's[8] use of the Paquelin cautery and the later use of the heavier electric cautery were possible only with the patient under an anesthetic, and again meant hospital treatment. Dickinson[9] deserves great credit for demonstrating and bringing to the attention of the profession the possibility of using the nasal type cautery tips as an office procedure in the treatment of various cervical conditions. Following his report in 1921, I began a rather cautious test of this method. While the early use in the office was not entirely satisfactory, largely because of timidity and a noisy transformer, later, with a proper equipment and more experience, the results improved and confidence in the method was established.

The technic used in our office is briefly as follows: After a suitable bivalve speculum has been inserted, the mucous discharge is thoroughly removed with cotton balls and applicators. A suitable light weight cautery tip, preferably from one-half to three-fourths inches (13 to 19 cm.) long, is placed firmly against the tissue to be destroyed and the current turned on by pressing the button on the cautery handle. As a sufficient depth is reached, the tip is gradually moved so as to make a line through the diseased tissue. In many cases it is necessary to cauterize only the glands near the external os and the eroded area; in others, the disease extends to the internal os. If at any time the patient complains of discomfort, the contact button is released and the current not applied again until she is comfortable. This process is continued until a sufficient number of cautery lines have been made. Nabothian cysts are destroyed in a similar manner after they have been punctured with the heated tip. An effort is made to reach the depth of the glands so as to destroy a part of the diseased tissue and all the bacteria. The lines are at least three-sixteenths inch apart, so that only a part of the cervical glands are destroyed. This permits regeneration of fairly normal glands. If the patient is very nervous or conscious of considerable pain, we administer nitrous oxide-oxygen analgesia or anesthesia in the office. Only a few patients are now being sent into the hospital for cautery treatment. In many ways the analgesia is more satisfactory than complete anesthesia for the office patient. She can administer it herself according to the technic formerly described for self administration during normal labor.

Since making our first report,[10] in December, 1924, an additional 180 patients, making a total of 317, have been treated by this method by my associate, Dr. Cron, and myself. A considerable number of these required two treatments, a few, three; and one had four before healing was complete and permanent. One hundred and nine patients delivered by us have been cauterized before being discharged. We have both observed that satisfactory healing occurs more promptly in patients cauterized within eight weeks after delivery. Twenty-six patients are known to have become pregnant since the cautery treatment. Of these, five had early abortions and two miscarried during the sixth month, but all seven had a history of one or more previous abortions. Six patients were pregnant at the time of treatment and two of these aborted, one within forty-eight hours and the other six weeks later. Cautery treatment is used only during pregnancy for bleeding polypoid areas, and is limited to the region of the external os. A few cases of long continued sterility have apparently been cured by the cautery treatment.

Following a cautery treatment, there is a marked increase in the discharge for about two weeks, and the patient is warned to wear a napkin. She is told that the next period may be more profuse than normal. A few patients have had excessive bleeding and have required a pack for a few hours. The patient is instructed to keep clean by frequent washing of the external genitalia. Douches are of questionable value, and as a rule women are warned against their use. We have found it advisable to clean out the vagina and cervix every week or ten days and to paint the cauterized area with mercurochrome-220 soluble or compound tincture of benzoin until healing is complete. A second cautery treatment is rarely indicated under four weeks, and very few require any more. Failure to clean out the cervix during the process of healing may result in a stricture of the external os. We have had to dilate the cervix in four patients who were not under observation following repeated cautery treatment. The cautery should never be used during the acute stage of a cervical infection. Patients with retroflexion should not be cauterized until the uterus has been replaced and a proper pessary inserted. Subacute salpingitis contraindicates the cautery. Sex trauma should be avoided for at least two weeks after the treatment, and in extensive cases longer. The cervix should never be cauterized during an operation in which the uterosacral ligaments are to be shortened. Syphilis of the cervix contraindicates the cautery.

It is our present practice to have puerperal patients that show any sign of cervical disease on the examination five or six weeks after delivery return in two or three weeks for another inspection and cautery treatment, if it seems indicated. This prophylactic measure may prevent more serious disease of the cervix in the future and is recommended.

This treatment is not considered a cure-all, but our experience with it has been so favorable that we rarely advise a cervical operation unless other surgery is needed. If a satisfactory result is not obtained, one may still resort to the Sturmdorf excision, tracheolorrhaphy or some type of amputation. We have operated on the cervix of only four patients who were previously treated with the cautery. Three were in the hospital for other surgery, and the cervix was repaired or amputated as an incident in the operation. One was sent in for a Sturmdorf excision about seven weeks after a rather superficial cautery treatment because of the patient's impatience and desire for the quickest possible relief. She was cured of her cervical discharge, but after a year is still sterile. This is the most satisfactory gynecologic treatment possible in an office, and I know of no other single procedure that has given such gratifying results.

CARBON MONOXIDE POISONING FOLLOWING ETHYLENE ANESTHESIA*

WILLIAM O'NEILL SHERMAN, M.D.
CHARLES M. SWINDLER, M.D.
AND
W. S. McELLROY, M.D.
PITTSBURGH

Recently, serious complications following ethylene anesthesia were encountered, with at least one fatality; another case which, in the light of subsequent events, could be ascribed to the same cause, and a third case in which the patient was dangerously asphyxiated.

The clinical and laboratory findings point to carbon monoxide as the causative factor. We are not aware that any previous reference has been made to carbon monoxide as a source of difficulty in the use of ethylene in anesthesia. Therefore, this preliminary report is made for the purpose of calling attention to this grave possibility, and the necessity for more careful control of the purity of the ethylene used.

CLINICAL FINDINGS

Case 1.—A white man, aged 39, of average weight and medium height, was admitted to the hospital suffering from a compound, comminuted fracture of the left leg; laceration of the forehead, with possible fracture of the frontal bone; and extensive contusion of the left shoulder. The patient was in profound shock at the time of entering the hospital, but, under the usual methods of treatment, reacted favorably and, forty-eight hours after admission, was taken to the operating room for the purpose of reducing the fracture of the leg by the open method.

Ethylene anesthesia was used and was practically uneventful until after the operation was completed and the anesthetic was about to be withdrawn, when it was noted that the pulse began to thin out and become imperceptible. The respirations became slower and shallow, the anesthetic was withdrawn and forced inhalations of oxygen, with about 10 per cent carbon dioxide, were given as a restorative. The pulse and respirations suddenly stopped about five minutes after the foregoing symptoms were noted. The period of anesthesia was fifty minutes.

The pupil, which was moderately contracted, and the reflex sluggishly active, suddenly dilated at the same time; the patient was cyanotic, the ears being rather pink. Artificial respiration with inhalations of carbon dioxide and oxygen continued for about ten minutes without any favorable response. Postmortem pallor appeared in the skin, and efforts at resuscitation were stopped.

On account of the fact that symptoms of collapse did not begin to appear until the operation was almost concluded, that there had been extensive comminution of the bone at the site of fracture, and that the symptoms of collapse were so sudden and came on without warning, the anesthetic was not considered an exciting factor, but a diagnosis of probable fat embolism was made as the cause of death. It is felt that this diagnosis should be revised in view of the experience in cases 2 and 3, in which the patients were anesthetized from the same lot of gas.

Case 2.—A man, aged 25, sustained a fracture of the external *malleolus, the injury occurring about ten days previous to* the operation, which consisted of reduction of the fractured malleolus.

Ethylene anesthesia was used. The patient was somewhat nervous; induction was stormy, with considerable secondary excitement. The pulse ranged between 100 and 120. No marked complications of anesthesia were evident beyond the undue excitement until the operation was finished and the anesthetic had been withdrawn. The period of anesthesia was twenty-five minutes. At the conclusion of the anesthesia, it was noticed that the patient did not revive promptly on administration of carbon dioxide and oxygen, but the respirations were quite shallow and the patient cyanosed. The patient was held in the operating room for observation for two or three minutes, when it was noticed that while there was still some tendency toward cyanosis, respirations were more free and regular, and he was returned to the ward.

Case 3.—A young adult was anesthetized with ethylene. The induction was somewhat stormy; the patient vomited after ten minutes of anesthesia, and then settled down to an apparently uneventful course. After twenty minutes, it was noticed that the pulse was becoming thin and thready and had risen to 135 beats a minute. Respiration was shallow and slow. The anesthetic was immediately withdrawn, and resuscitation measures—inhalations of pure oxygen with 10 per cent carbon dioxide, were substituted. The patient had about five voluntary respirations of this mixture, and suddenly ceased breathing, the pulse stopping simultaneously and the pupil immediately dilating. Forced artificial respirations with carbon dioxide and oxygen were continued for about ten minutes without favorable result.

In this case, a peculiar cherry red color was noticed in the skin of the entire body, especially on the chest, which confirmed the suspicions already engendered that there might be some toxic agent in the anesthetic. After ten minutes of artificial respiration, the cherry red started to fade, and postmortem pallor and lividity began to appear. Artificial respiration was then stopped.

Fifty cubic centimeters of blood was immediately withdrawn from the heart chamber of patient 3, and the same amount was taken from the vein of patient 2, who had been sent down to the ward a half hour previous. These specimens were sent to the hospital laboratory, and tests for carbon monoxide were positive, as given in the laboratory report.

LABORATORY FINDINGS

Results of Examination of the Blood.—On dilution of the blood with water and on comparison in test tubes with a similar dilution of normal blood, a definite cherry red, characteristic of carbon monoxide hemoglobin, was observed. The blood from both patients gave strong positive reactions for carbon monoxide hemoglobin with the following reagents: sodium hydroxide, potassium ferrocyanide, tannic acid, phenol (carbolic acid), phenylhydrazine, and phosphotungstic acid. Spectroscopically, the presence of carbon monoxide was shown by the behavior of the blood toward reducing agents. The quantitative saturation of the blood with carbon monoxi was determined by means of the colorimetric method developed by the United States Bureau of Mines. The blood from patient 1 showed 50 per cent, and from patient 2, 60 per cent saturation with carbon monoxide.

---

* From the surgical and laboratory departments, St. Francis Hospital.

Examination of Ethylene for Carbon Monoxide.—The cylinder of ethylene used when delivered to the laboratory was practically empty; therefore, an adequate amount for thorough examination was not available. Bubbling about 3 or 4 cc. of the gas through a solution of hemoglobin failed to show the presence of carbon monoxide. The cylinder was submitted to the Mine Safety Appliance Company of Pittsburgh, which evacuated the residual gas and, using a combustion chamber, found a carbon monoxide concentration of 0.7 per cent.

Two other fresh stock cylinders of ethylene, labeled 1 and 2, were examined for carbon monoxide, with positive results. No. 1 cylinder bore the same manufacturer's serial date as the cylinder used in the cases reported; no. 2 cylinder, a different serial date.

A guinea-pig was placed in a small respiration chamber, which was attached to the apparatus used in administering the ethylene to the two patients. In this manner anesthesia was induced in the guinea-pig, with the same ethylene-oxygen mixture as administered in the cases reported. The anesthesia was maintained for about one hour. With cylinder 1, the guinea-pig died after one hour of anesthesia. Blood was withdrawn from the heart, and the qualitative tests used on the patients' blood gave strongly positive reactions for carbon monoxide hemoglobin. Quantitative examination showed 70 per cent saturation with carbon monoxide. Furthermore, by bubbling the ethylene directly from the cylinder through normal human blood, typical tests for carbon monoxide hemoglobin were obtained.

Cylinder 2 was used, and the guinea-pig, still alive after one hour of anesthesia, was removed from the respiration chamber, and blood was withdrawn from the heart. This blood gave the typical reactions for carbon monoxide hemoglobin and quantitatively about 50 per cent saturation with carbon monoxide.

COMMENT

The apparatus used in the three cases is an approved type wherein the gases are bubbled through water and mixed in a common chamber with a sight-feed control. The usual mixture is, approximately, from 15 to 20 per cent oxygen and from 80 to 85 per cent ethylene, with carbon dioxide added up to 5 per cent, as indicated by the depth and number of respirations of the patient. Nitrous oxide is used for purposes of induction only and is seldom continued more than three minutes.

The routine preanesthetic narcotic medication, consisting of one-fourth grain (16 mg.) of morphine, and 1/150 grain (0.4 mg.) of atropine given hypodermically one-half hour before operation was given in the first two cases, but in case 3, morphine was reduced to one-sixth grain (11 mg.) on account of the age and body weight, which was somewhat below the average.

The death of the first patient, as mentioned, was ascribed to possible fat embolism, but on account of the similarity of the symptoms between this case and the fatal third case, and also the fact that the gas was administered from the manufacturer's same serial number, it is felt that the first case should be regarded as an anesthetic fatality rather than due to embolism.

The second patient recovered.

In all three cases, the signs of collapse did not occur until the operation was practically over and the anesthetic was about to be withdrawn.

The clinical and laboratory findings point to carbon monoxide as the cause of the complications encountered in the cases reported. The possibility that ethylene combines with hemoglobin, forming a compound which simulates carbon monoxide in its reactions, was considered, but excluded on the basis of Luckhardt's observations, as well as our own.

Furthermore, we have considered the remote possibility that we might be dealing with some impurity in the ethylene other than carbon monoxide which combines with hemoglobin, forming a compound which reacts like carbon monoxide hemoglobin. We are not aware of any known substance of this nature. Such a substance, if it exists, would undoubtedly affect the respiratory function of the blood as does carbon monoxide and, therefore, have the same poisonous effect.

The whole problem is being further investigated in collaboration with the United States Bureau of Mines at Pittsburgh.

Clinical Notes, Suggestions, and New Instruments

DIABETES MELLITUS ASSOCIATED WITH STATUS LYMPHATICUS *

Ralph H. Major, M.D., and Ferdinand C. Helwig, M.D.,
Kansas City, Kan.

A great many complications have been described as occurring in diabetes mellitus. Many of these complications may be regarded simply as coexisting conditions, while others seem to bear a definite, direct relationship to the disease itself. The following complication, which we have recently observed, probably belongs to the latter group and is apparently very unusual.

REPORT OF CASE

D. D., a girl, aged 11, who was admitted to the medical service of Bell Memorial Hospital, Oct. 22, 1925, at 7 a. m., and who died four hours later, had suffered from diabetes for approximately two years. During this time she had had a moderately severe form of the disease, but had been kept in good condition by dieting and insulin therapy. She had gained weight and grown in height at a satisfactory rate. In September, 1923, her height was 44½ inches (113 cm.) and her weight 44 pounds (20 Kg.); in May, 1925, her height was 48½ inches (123 cm.) and her weight, 48½ pounds (22 Kg.). There was a history of occasional attacks of asthma beginning in 1918, which were becoming increasingly infrequent.

The patient had not felt well for a day preceding her death, and in the afternoon vomited once and went to bed. Late that afternoon, she dressed and felt very much improved. She ate some dinner and afterward played with her playmates. In the evening, on going to bed, she appeared slightly abnormal but, following a dose of 15 units of insulin, she seemed normal and went to sleep. At 7 a. m., it was impossible to arouse her, and she was immediately brought to the hospital, with the clinical appearance of diabetic coma.

The child was unconscious, her temperature was 104.6, and her pulse was 140. The blood sugar was 645 mg. per hundred cubic centimeters, and the carbon dioxide tension was too low to be read accurately but was approximately 4.5 per cent by volume. The child's breathing was stertorous, becoming increasingly difficult, and she died without regaining consciousness in spite of the insulin and alkalis administered.

The necropsy findings showed edema of the lungs, some cloudy swelling, and fatty degeneration of the liver. The kidneys were normal. The thymus was unusually large, covering the entire surface of the pericardium anteriorly and weighing approximately 50 Gm. The pancreas showed grossly nothing abnormal. The kidneys were normal on gross inspection. There was a distinct enlargement of the abdominal lymph glands, especially those in the mesentery.

A microscopic section of a lymph node of the mesentery showed a chronic inflammatory reaction. The lymphoid tissue was broken up into lobules by heavy bands of fibrous tissue. The peripheral sinuses were dilated and contained leukocytes, mostly of the mononuclear type. There were groups of leukocytes in the surrounding fat tissue, and eosinophils also were present. A microscopic section of the thymus gland showed numerous Hassall's corpuscles, which were very large and showed some hyaline degeneration. There was marked endothelial cell hyperplasia, particularly in the medulla. A section through the pancreas showed no marked pathologic changes, except for striking diminution in the number of islands of Langerhans. Many sections through both the head and the tail of the pancreas were studied before any islands were seen. No definite evidence of regeneration of the islands of Langerhans was seen.

---

* From the Departments of Internal Medicine and of Pathology, the University of Kansas School of Medicine.

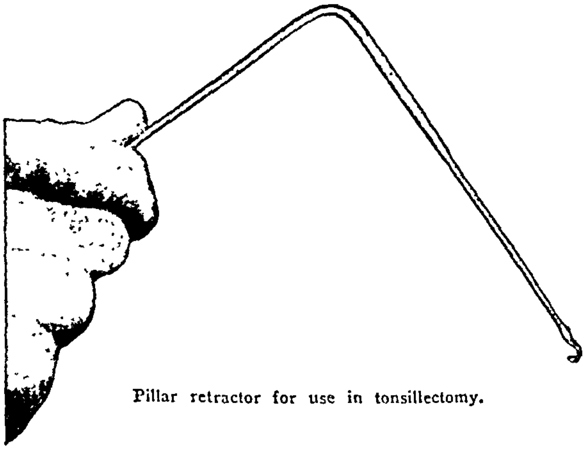
The most striking features of the postmortem examination were the marked enlargement of the thymus, enlargement of the abdominal lymph glands, edema of the lungs, and the microscopic evidence of diminution of the islands of Langerhans in the pancreas. The size of the thymus, together with the lymphatic enlargement, is sufficient to justify the diagnosis of status lymphaticus associated with diabetes mellitus.

It would seem possible that status lymphaticus in this patient bore some definite relationship to the disease. There is much evidence of the relationship between diseases of the various glands of internal secretion. Although we have no knowledge regarding the physiologic action of the thymus, it probably bears some definite relationship to the endocrine system, of which the pancreas is an important member. Patients suffering from status lymphaticus have notoriously little resistance to disease or trauma. It is possible that the extremely rapid onset of coma in this patient may have been due to such lessened resistance. It is also a matter of interest that the patient had numerous blood examinations and a very large number of insulin injections without any bad effects from these slight traumas. The attacks of asthma from which the patient suffered were probably of the thymic type.

A CONVENIENT PILLAR RETRACTOR

CHARLES EVERETT HAINES, M.D., NEW ROCHELLE, N. Y.

The pillar retractor in common use for tonsillectomy is unsatisfactory. Its straight handle many times brings the hand of the assistant who is wielding it directly into the line of the surgeon's vision, and, in any case, fills valuable space over the limited field of operation.



Pillar retractor for use in tonsillectomy.

Thus, the tonsillar fossa is not always satisfactorily exposed; bleeding points may remain undiscovered and unligated, and residual tabs of tonsillar tissue may be overlooked.

With these things in mind, I had the handle of a Hurd retractor bent to an angle of 90 degrees. This was done in a few minutes by an electric welder. The new instrument thus formed is much more satisfactory than the straight-handled one; with it, the assistant's hand keeps well to one side, out of the surgeon's line of vision and out of the way of his hands.

I have assisted and have been assisted with this new instrument many times; the invariably good results have demonstrated its superior convenience.

Special Article

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(Continued from page 1692)

RECTAL ADMINISTRATION

Medicaments may be introduced into the rectum for one of three purposes: for systemic action, for local medication, and for exciting evacuation. As the function of the rectum is expulsion rather than retention, it is obvious that ordinarily special measures have to be employed to secure local medication of the colon (endocolonic action) or systemic medication by the colon (diacolonic action). There are, however, certain persons—those suffering from torpor recti (dyschezia of Hertz)—whose lower bowel is extraordinarily insensitive and retentive. In these, exciting evacuation may be more difficult than securing retention. With certain other patients the rectum is excessively irritable, as in various forms of proctitis, in which it may be very difficult to have medicaments retained. Hence it is a good rule to make a digital examination of the rectum before resorting to rectal medication. In this manner, excessive irritability that would require unusual care to secure retention of the medicament can usually be detected; or, if the rectum is filled with feces and the patient has no desire to defecate, torpor recti may be diagnosticated. A rectum distended with fecal matter should first be cleaned out by an evacuant enema before it is given the task of receiving medication.

As the rectum is capable of a considerable degree of absorptive activity, this form of systemic administration may be resorted to when the stomach is nonretentive on account of vomiting; likewise when it is desired to spare the stomach and intestine from the action of the drug, or to protect the drug from the action of the digestive ferments. With children, who will not take disagreeable tasting medicaments, or with the insane, who refuse to swallow, rectal administration may become an important recourse. Such a bitter substance as strychnine can best be given to children in suppository form, provided this method of administration is carried out gently, skilfully and tactfully. Unfortunately, quinine is too irritant to the colon to be relied on in the treatment of malaria. It will either be rejected or produce proctitis and colitis, its absorption in either case being interfered with. Sometimes anal fissure, inflamed hemorrhoids or cancer make rectal administration so painful as to be inexpedient unless demanded by the condition itself.

The dose by rectum is generally assumed to be double that by the stomach; but an exception has to be made in the case of certain alkaloids, such as strychnine and morphine, as well as phenol, which are reported to be more toxic when given by rectum than when administered by mouth. This is explained as due to circumvention of the destructive action of the liver on these substances, part of the burden of absorption being carried on through the inferior hemorrhoidal veins.

---

* This is the twenty third of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

It is obvious that the technic will differ according to whether we aim at procuring evacuation of intestinal contents or at securing retention of the injected material. The term "enema" is applied to liquids used for either of these purposes; hence, we must distinguish between evacuant enemas and retention enemas. Ointments are introduced into the rectum chiefly for topical use. Enemas require some form of syringe, ointments a special tube for introduction. Suppositories, which are solids conveniently shaped for insertion into the rectum, require no apparatus. Hence they may be considered the preferable form of rectal administration, unless special reasons render other forms desirable.

SUPPOSITORIES

Suppositories, in the widest sense of the word, are conveniently shaped solid preparations intended for medication of mucous cavities other than the mouth. Thus there are urethral, vaginal, aural, nasal and rectal suppositories. As the others are rarely used, the name, unless otherwise specified, implies rectal suppositories. These are generally small, cone shaped bodies weighing, according to the U. S. Pharmacopeia, about 2 Gm. (French Codex, 3 Gm.) and certainly not exceeding 5 Gm., and of such consistency as to be solid at room temperature but fluid at the temperature of the body. For infants, they are generally made about half the size prescribed for adults (from 1 to 2.5 Gm.).

Evacuant Suppositories.—Though suppositories are less commonly employed for evacuation than for retention, there are at least two evacuant suppositories of sufficient importance to require mention. The official glycerin suppositories are simply glycerin (3 Gm.)[56] solidified by a small amount of hard soap (sodium stearate) so as to permit shaping it into form convenient for introduction into the rectum. They are obviously less troublesome to use than fluid glycerin, though probably also less efficient. A teaspoonful of pure glycerin, even less (from 2 to 5 cc.), injected into the rectum by means of a small syringe produces within one to fifteen minutes (average, eight) evacuation in perhaps 75 per cent of patients. The evacuation is due to local irritation of the rectal mucosa, caused partly by the hygroscopic and partly by the chemical nature of the glycerin. That it is not merely a question of osmosis is shown by the fact that other solutions of high osmotic tension, e. g., concentrated sodium sulphate solutions, placed into the rectum in a similar manner did not produce evacuation. Frequent repetition of this irritation may result in increased irritability of the rectum, which might be of advantage in torpor recti[57] but would be objectionable under other conditions. Glycerin suppositories are generally carried in stock by druggists, protected in some way against atmospheric moisture. This may be secured by wrapping them in tin foil, covering them with paraffin, or inserting each one in a small glass tube stoppered at both ends.

Soap suppositories, fashioned in the home from any kind of good soap, furnish a simple and convenient means for occasional stimulation to rectal evacuation, perhaps not used commonly enough. Very frequent use of these in any one patient might possibly be as objectionable as that of glycerin suppositories.

Retention Suppositories.—For suppositories that are to be retained, the most generally useful vehicle is oil of theobroma (cacao butter), a solid at ordinary room temperature whose melting point is about 93 F., just a little lower than the normal temperature of the human body. Glycerinated gelatin is sometimes used, especially for urethral suppositories, for which cacao butter is too brittle. Suppositories made with glycerinated gelatin usually weigh about twice as much as those made with oil of theobroma.

Because of their convenience to the patient, suppositories are the preferred rectal administration form whenever the medicine to be given meets the following essential requirements:

1. Liquids cannot be administered in suppository form, unless their dose does not exceed a few drops. In case it does slightly exceed this limit, e. g., solution of epinephrine, it is well to permit the addition of a little hydrous wool fat or to use glycerinated gelatin.
2. The dose must not be bulky. As a general rule, it should not exceed 20 per cent of the weight of the suppository. A maximal quantity of active ingredients would therefore be 1 Gm.; but usually not as much as this is prescribed. Bromide, iodide or salicylate is generally not considered suitable for suppository form.
3. The drug must not be very irritating, or it will not be retained.
4. The drug must not lower the melting point of cacao butter, as do all drugs which dissolve in it, as fixed and volatile oils, phenol, creosote or chloral hydrate. This could, if required, be rectified by the addition of wax (from 10 to 20 per cent), which raises the melting point of the mixture.

For the rectal administration of substances not suitable for suppository form, we have recourse to ointments or enemas. Drugs administered in suppository or ointment form are absorbed more slowly than when given in solution as an enema.

Suppositories are prepared in one of three ways: (1) by the cold process, (2) by melting, or (3) by filling suppository capsules.

In the cold process the active ingredients, sometimes made into a paste with a small quantity of solvent, are mixed and pounded together with the grated oil of theobroma, the mixture being worked actively with the pestle until the mass is homogeneous and plastic like a pill mass, a small quantity of expressed oil of almond being added, if necessary. Then the mass is either pressed into proper shape by means of a little machine made for the purpose or rolled into a cylinder, at first in the palm of the hand, and then on a smooth hard surface. The cylinder is then cut into the required number of equal parts. Finally, one end is pointed by being gently pressed into shape with the thumb and finger, and the other slightly rounded. There are simple machines on the market that shape a suppository mass more rapidly and uniformly than can be done by hand. Lycopodium is used as a conspergative in the same way as in making pills. If, during the process of preparation, the mass becomes brittle and begins to break, plasticity may be restored to it by working it in the hand; if, however, it is handled too much, the mass becomes too soft for satisfactory manipulation.

When melting is resorted to in the preparation of suppositories, the oil of theobroma is melted first; then the active ingredients are added, and the mixture is stirred until it just begins to congeal. It is then poured into molds chilled by ice. The chief disadvantage of this process is the tendency for the settling and uneven distribution of the active ingredients. This is minimized by closely following the directions given. Glycerinated gelatin suppositories, of course, can be made only by this process.

---

[56] Manufacturers also place on the market glycerin suppositories of smaller size, suitable for infants.

[57] The graduated glycerin enema, suggested in this condition, is administered every morning after the patient has attempted to move the bowel. If he fails, 30 cc. of glycerin is injected. If this proves successful, the next morning a teaspoonful of glycerin is replaced by a teaspoonful of water, and on successive days the reduction in the strength of the glycerin is continued, until eventually 30 cc. of water without glycerin is used. By this time, the patient is generally cured.

Suppository capsules made of oil of theobroma or of gelatin are on the market. They are filled like other capsules. While they are less troublesome to prepare, they are less desirable than suppositories prepared in the other ways, as the medicament is not incorporated throughout the mass; hence the action is less uniform, and an irritant less diluted is more irritative.

The prescribing of suppositories does not differ much from the prescribing of pills, excepting that the excipient is always specified and its quantity generally as well. It may be laid down as a general principle that suppositories should be made as small as possible (2 Gm. or less) unless the medicament is irritative or caustic, when making the suppositories larger (not over 5 Gm.) will lessen the irritation and favor retention. In the subscription we merely state: "Mix and divide into —— suppositories," to which it is well to add "with the edges of the base rounded off." It is unnecessary to specify by what process they are to be made. Cacao butter suppositories are generally dispensed resting on cotton in pasteboard boxes. Glycerinated gelatin suppositories should be protected against dryness as well as moisture by being kept in an air tight container.

Directions to the Patient.—While the transcription usually merely indicates the frequency of administration, explicit verbal directions are given concerning the place and mode of introduction. The usual mode of introduction pointed end first has the disadvantage that, unless the base of the cone is pushed beyond the internal sphincter the whole suppository will be rejected. If, on the other hand, the base of the cone has rounded edges, and this—the larger end—inserted first, as suggested by Gilbert,[58] the suppository is virtually sucked into the rectum, as soon as its widest circumference has passed the sphincter, making it unnecessary to insert the introducing finger into the rectum, as is the case with the usual method. Anointing the cone with oil just before use facilitates its introduction. As cacao butter melts at a temperature above 30 C., suppositories should be kept in a cool place until they are used.

The following examples may serve to illustrate the prescribing of suppositories:

Anodyne suppositories composed of opium, 0.1 Gm., and extract of belladonna, 0.03 Gm., advantageously with the addition of cocaine hydrochloride, 0.01 Gm., are employed preceding a bowel evacuation in painful conditions of the rectum.

Sedative suppositories are at times useful in the treatment of vomiting; e. g., codeine phosphate, 0.06 Gm., or phenobarbital sodium, 0.25 Gm., or the two combined.

In prescribing astringent suppositories for bleeding hemorrhoids, 10 per cent of tannic acid should not be exceeded, or else the suppository becomes too irritative.

OINTMENTS FOR RECTAL ADMINISTRATION

Ointments may be applied to the rectum and anal margin by means of the anointed finger gently introduced through the sphincter. Or, better, the ointment may be dispensed in a collapsible tube, such as is used for holding artists' colors. To the end of this tube is fitted a cone shaped tip or a small piece of soft rubber tubing, which is inserted into the rectum. By pressure on the collapsible tube, the ointment may be forced into the canal without difficulty. A hollow cone, sometimes called "pile pipe," may be employed. Generally this is made of hard rubber, having multiple perforations near its tip, while its base is fitted with a sort of plunger which, on being screwed in, forces the ointment out of the holes at the top.

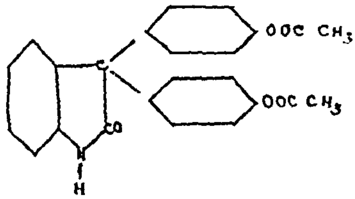
The following examples of rectal ointments may suffice: An ointment for local anesthesia of painful rectal ulcer may be composed of 5 per cent benzocaine in hydrous wool fat. As astringent ointment in treatment of bleeding hemorrhoids, the nutgall ointment (20 per cent) of the U. S. Pharmacopeia is at times useful.

(To be continued)

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

ISACEN.—Diacetyldioxyphenylisatin —



The diacetyl derivative of dihydroxyphenylisatin. The compound resembles phenolphthalein in that the isatin group has somewhat the same general grouping as that of the phthaleins, unlike phenolphthalein, in isacen the two hydroxy radicals (of the two phenol groups) have been condensed with two acetyl groups

Actions and Uses —Isacen passes through the stomach unchanged when it reaches the intestine, a gradual splitting off of dioxyphenylisatin takes place under the influences of the alkaline contents of the intestine. The dioxyphenylisatin thus produced is stated to be nontoxic, not to be absorbed, and to be excreted entirely through the feces: neither dioxyphenylisatin nor the acetyl compound isacen appears in the urine after administration of isacen. Isacen acts as a laxative or purgative, depending on the dosage employed.

Dosage —As a laxative, 0 005 Gm.; in cases of obstinate constipation, from *0 015 to 0 02 Gm. Isacen is supplied in* the form of tablets only.

Manufactured by the Hoffmann LaRoche Chemical Works, New York. U S patent applied for U. S trademark 200,220

Isacen Tablets 0 005 Gm

Isacen is a white, crystalline, odorless, tasteless powder. It is insoluble in water and dilute hydrochloric acid, slightly soluble in alcohol, very slightly soluble in ether It melts at 241 to 242 C.

Boil 0 1 Gm of isacen with 3 cc of sodium hydroxide solution; cool, dilute to 10 cc. with water. on the addition of a few drops of potassium ferricyanide solution (1 in 10), a cherry red color results Boil 1 Gm of isacen with 10 cc of sodium hydroxide solution; cool, add an excess of diluted sulphuric acid; the odor of acetic acid develops Dissolve 1 Gm of isacen in 20 cc of glacial acetic acid and maintain at 100 C.; a clear solution results *(limit of dioxyphenylisatin)* Boil 1 Gm of isacen with 50 cc of distilled water, no odor develops Cool the solution, add sufficient water to restore the volume of 50 cc ; filter, and to 10 cc of the filtrate add a few drops of silver nitrate solution; no opalescence is produced immediately *(chloride)*. Transfer 2 Gm of isacen to a glass stoppered cylinder, add 50 cc. of distilled water, shake for five minutes and filter through paper To 25 cc. of the filtrate add one drop of phenolphthalein solution; on the addition of one drop of tenth normal sodium hydroxide solution, a pink color results *(limit of acid)*. Incinerate about 1 Gm accurately weighed. The ash should not be more than 0 5 per cent

DIET AND HYPERTENSION IN RENAL INSUFFICIENCY

The kidneys are charged with the function of eliminating certain types of waste products, notably the end-products of protein metabolism, from the body. It may be assumed, therefore, that these organs possess a large factor of safety in respect to their capacity to excrete continually varying quantities of nitrogenous and inorganic compounds in solutions exhibiting a wide range of difference in reaction. The organism in health depends on the kidneys for the removal of excess of fixed acids or bases as a part of its essential acid-base equlibrium. It would be unlike any other fundamental physiologic function if the mechanism to accomplish this were not adapted to liberal variations in the tasks that may be committed to it. On the other hand, one may readily understand that disorganization or destruction of any organ thus important would lead to serious consequences, particularly when the functions involved cannot well be vicariously assumed by other structures. In the case of the nitrogenous and inorganic catabolites, the other excretory organs—the skin, lungs and bowel—at best can exert insignificant action.

It can readily be understood, therefore, why certain restrictions of diet have been advocated in the management of certain types of renal disorder. The principle of "sparing" a weakened organ has been put into practice. Nor has this been all. As if to forestall possible deterioration through continued involvement in active excretory functioning, a highly moderated regimen has been recommended even for the healthy. The low-protein diet has been advocated as an insurance against the menace of the unremitting necessity of eliminating nitrogenous waste, not merely in the form of organic compounds but also as the excess of acid catabolites to which protein breakdown characteristically gives rise.

Chronic kidney disease manifested by renal insufficiency may be attended with certain other symptoms of an undesirable nature. Thus, it is well known that a gradual rise of blood pressure is usually observed in chronic glomerulonephritis. This has been attributed by some observers to progressive atrophy of renal tissue. As Anderson[1] has recently pointed out, the real cause of the progressive development of renal insufficiency in chronic nephritis is not clear. One view is that it is due to repeated infections. Day holds that it is due to a specific infection. Bell believes that each new infection occurring in a nephritic patient causes closure of more glomerular capillaries and leaves the patient with a smaller kidney filter than before. Carter, Howe and Mason suggest as a possibility that progressive injury to the kidneys may result from repeated minimal injury by means of irritating food substances, some of which are known and others as yet unrecognized. Injury to the remaining functioning tissue by high concentration of retained metabolites or by overactivity are other possible causes of the progressive development of insufficiency. It is admitted that there is likely to be a concentration of nonprotein nitrogenous substances, such as urea, uric acid and creatinine, higher than normal in the blood of the affected patients. Are these per se or their protein precursors directly responsible for the various pathologic manifestations? If not, has the emphasis placed on "high protein" tended to obscure the possible significance of entirely different etiologic factors?

To what extent diets unusually rich in protein may actually induce detrimental conditions must still be regarded as highly debatable. There are writers who, like Newburgh of Ann Arbor, insist that the human kidney may be injured by protein excess. There is the added suggestion—as yet it cannot be dignified with the designation of compelling evidence—that alleged renal injury is attributable to the excretion of "nephrotoxic amino-acids." Certain cogent experimental tests[2] warn against hasty generalizations. It is conceivable that bacteria as well as diet may injure. Furthermore, the added conclusion that hypertension and arteriosclerosis are due to the same factors is an as yet unwarranted jump.

Problems of etiology and treatment are likely to receive a more ready solution whenever the conditions under investigation can be experimentally duplicated. The history of medicine abounds in illustrations of this. Progress has often been delayed in the interpretations of those diseases for which an experimental counterpart is not attainable. This is to a large extent the case in the study of human renal disorder. Nephroses are readily produced by uranium salts, potassium chromate, chloroform and many other substances, but these conditions do not give a chronic renal insufficiency. The nearest approach to chronic types has been secured by removing or destroying a large part of the renal tissue. The kidney cortex can be reduced any desired amount and a proportion found that will simulate the reduced filter found in chronic nephritis. But the two conditions are not exactly similar; in chronic nephritis practically all of the glomeruli are at least partially closed, whereas, following partial nephrectomy, the small number that remain are entirely normal.

[2] Jackson, H, Jr, and Riggs, Margaret D: The Effect of High Protein Diets on the Kidneys of Rats, J Biol Chem **67**: 101 (Jan) 1926.

Anderson[3] has recently demonstrated that removal of two thirds of the kidney substance in rabbits results in a retention in the blood of urea and creatinine, which either increases progressively in intensity until death results, or decreases progressively until normal values are once more attained. If the renal insufficiency is not progressive, the kidney remnant undergoes hypertrophy. A high protein diet causes no further change in the kidney remnant than further to augment the hypertrophy. Such a diet causes a retention of creatinine and urea in the blood in rabbits from which a portion of kidney substance has been removed. It is proportionate to the amount of kidney that has been removed. The retention does not occur in normal animals. The finding deserving of most emphasis in this connection, however, is that hypertension is not caused in rabbits by renal insufficiency per se; nor by a high protein diet even in the presence of a low renal function; nor by prolonged retention of creatinine and urea in the blood. A marked atherosclerosis of the aorta may ensue, but it is not chargeable to the chemical changes in the blood just described. For the present, the reference of high blood pressure to the concentration of the usual blood metabolites must still be subject to large reserve of statement and to openmindedness.

WHISKY—THEN AND NOW

Soon after the passage of the federal Food and Drugs Act of 1906, the formulation of definitions for various products likely to come under the suspicion of the enforcement agents became a pressing and highly debated problem. It early included the question of what constitutes whisky. After considerable controversy the simple official conclusion was reached, in effect, as Bailey[4] has expressed it, that the commodity which was then, and which had been for many years, commonly known and accepted in the trade and among consumers as whisky, was whisky. This interpretation did not limit the name to that product aged in wood whereby the aroma and flavor for which whisky is prized are acquired; nor did it make the natural color developed by the aging process an essential. Thus, factitious whiskies made largely, or in part, from mixtures of grain alcohol, caramel, beading oil and artificial flavor were widely sold as, and for, whisky long before prohibition became operative. The same government chemist has pointed out that, presumably under the influence of the Volstead Act, whisky and brandy, which had hitherto been recognized as medicinal agents and included in the United States Pharmacopeia, were omitted in the ninth revision of that text. But, in view of the fact that both of these commodities are legitimately obtainable under proper restrictions, it would be unfortunate if there were no official specifications for their substance and quality, and in the present (tenth) revision of the Pharmacopeia these two products are again recognized.

Through circumstances that do not require discussion here, it happens that alcoholic fluids alleged to be whisky have not been entirely excluded from use as beverages. The fact that most of both the manufacture and the traffic in such products is conducted in illicit ways has led to widespread possibilities of "adulteration" that may have unexpected menaces to the health of those willing to indulge in the bootlegger's wares. The real danger in the substitution of methylated spirit, or wood alcohol, for ethyl alcohol in potable fluids is now generally recognized.[5] Not long ago we referred to the unexpected presence of considerable—perhaps even menacing—quantities of copper found in samples of "hooch" by government authorities in Massachusetts.[6] An informative investigation of samples of alleged whisky secured by police or prohibition officials in connection with the enforcement of state or federal laws has been reported from Connecticut.[4] Aside from a series of samples in which wood alcohol had been substituted for grain alcohol and all of which were traced to one source, no foreign substance was identified in "bootleg" liquor of the types ordinarily used as beverages, which in kind or amount could be regarded as a probable cause of death.

There is substantial analytic and other evidence to show that much of the alcohol used in preparation of present-day liquors is obtained by the rectification of denatured alcohol, particularly the specially denatured type. Such alcohol generally shows on analysis traces of denaturants that have carried over in the process of purification. What the physiologic effects, cumulative or otherwise, of these small amounts of denaturants may be is speculative, but the Connecticut chemists are aware of no authoritative opinion that traces of such substances as diethylphthalate, isopropyl alcohol, benzene and acetone are likely to produce measurable effects of a dangerous character. However, they insist that with the evidence that much of the alcohol found in intoxicating liquors is derived from the denatured article, there is always the possibility of inefficient purification, and hence such liquors constitute a potential source of danger. In nearly half of the samples tested the alcohol appears to have been derived wholly, or in part, from denatured alcohol.

[6] "Hooch," "Home Brew" and Copper, editorial, J. A. M. A. **86:** 1552 (May 15) 1926.

It is not without significance to compare the bar whisky of the cheaper sorts dispensed a decade or more ago with the stock in trade of the bootlegger. The average alcohol content is essentially the same. Artificially colored whisky was about as prevalent before prohibition as it is now. Perhaps some of these findings will help to interpret an experienced chemist's comment that "the most poisonous constituent of alcoholic liquors is the alcohol which they contain." Nevertheless it is well to bear in mind further the conclusion of Bailey that the possibility of clumsy manipulation of denatured alcohol in order to make it fit for beverage purposes constitutes a menace to health which cannot be ignored. This applies not only to whisky but to similar liquors, such as gin, brandy and cordials, of high alcoholic content, all of which may be produced factitiously.

TISSUE REACTIONS TO IRRADIATION

Remedies are frequently and justifiably employed in medicine before their exact mode of action is understood; but it is profitable and interesting to obtain definite knowledge as soon as possible, so as to regulate their use to the best advantage. Irradiation of tumors cannot be done to the fullest extent and with the most favorable results until its effects on tumor cells, normal tissues, and the body in general are accurately known.

The effects of irradiation on tumor cells have recently been considered in a summary of the subject by Dr. James Ewing.[1] Either a shrinking and pyknosis of the nuclei, or swelling from imbibition of fluids, resulting in degeneration or necrosis, are among the first of the occurrences in the tumor cells. Mitosis is stopped for a considerable period, even if the cells recover eventually. The exact physical chemistry of the cellular changes is not yet known, but in most cases they take place more readily in dividing than in resting cells, and especially in rapidly growing tumors Besides this primary injury, irradiation is followed by a secondary and more important injury, due to interference with the blood supply of the tumor. The blood vessels are the site first of inflammation and exudation, and then of induration, resulting in anemia of the tissue supplied. This factor is frequently underestimated in the destruction of cancers. The surrounding normal connective tissue receives some injury also, and the dose must be nicely adjusted so that, while the injury to the tumor cells is followed by necrosis, that to the normal tissue is followed by inflammation and repair. The reaction on the part of the lymphocytes and plasma cells is characteristic of beginning repair, and is followed in many instances by growth of connective tissue which completes the process.

The various systems of dosage differ in the tissue reactions which they call forth, and rational choice between them should be determined by the type of reaction desired. The prolonged single exposure to a moderate dose of hard rays is most efficient in killing rapidly dividing tumor cells and aborting growth, without causing much injury to normal tissue or stimulating a defense reaction. Smaller fractionated doses at intervals of a few days are intended to destroy the tumor cells by the cumulative effect of repeated injuries, and are accompanied by moderate tissue reaction. The method is safe and convenient. The single large killing dose gives the most impressive results, but the exact size of the dose needed for different kinds of tumors is a difficult matter to determine It causes marked destruction of the abnormal cells, with severe general tissue reaction, and is therefore a most effective method of treatment. The tissue reactions called forth by radium and by roentgen rays also differ, as the former acts chiefly on the actual tumor cells, while the latter stimulate the surrounding normal tissue to a greater degree.

The effect of irradiation on the body in general is also a factor to be considered and may be of considerable importance. The nutrition and metabolism are probably improved by the rays, and it has been suggested that a general nonspecific protein immunization is effected, whereby resistance of the body to the tumor is increased. At present the chief need seems to be for more exact histologic descriptions of the changes caused in different types of tumors by different doses of irradiation and methods of application, so that the mode of treatment best calculated to produce a desired result can be more accurately determined.

Current Comment

JUTE DERMATITIS

Even primitive man realized that certain occupations and trades may be dangerous to health. Hippocrates and Galen mentioned it, and Ramazzini's treatise on the diseases of occupation dates back to 1760. It is only in comparatively recent times, however, that detailed attention has been directed to the precise nature of the manifold menaces to health and longevity for which industrial conditions may be responsible. A higher value is being placed on human life. If the factors that tend to impair its length or efficiency are discovered, they can in many instances be amended or averted with hygienic benefit. Mere diagnosis of the pathologic condition is not sufficient for such progress; the causative agencies and their mode of action must be ascertained. Interest in special occupational diseases varies in different parts of the world, owing to the peculiarities in the distribution of the trades and vocations. The mines and chemical trades, for example, are not always or even commonly centered in the same geographic regions. Thus, it happens that the problems of vocational hygiene differ markedly in various countries of the world. An illustration of this is afforded by certain features of the jute mills. Aside from the annoyance of the dusts encountered in the production of cordage, twine, jute and similar materials, the occurrence of skin rashes caused by oils and coloring matter has been recognized though rarely referred to. In India, however, where in the provinces of Bengal alone there are more than 281,000 persons working in jute mills, registered under the factory act, jute dermatitis has attained a greater significance. According to Curjel and Acton[1] of Calcutta, this folliculitis, which does not ordinarily give rise to irritation or itching, is a nonsuppurative lesion caused by the mechanical blocking of the sebaceous gland orifices by plugs of the unexfoliated stratum corneum. The primary incitant is the mineral oil used for softening the jute; it does not irritate the skin, but protects the cutaneous surfaces from water and thus increases the accumulation of skin débris, particularly in the natives who do not cleanse their skins thoroughly with suitable detergents. The remedy is simple, so long as septic changes are not superimposed. The occupational affection of the skin in jute workers presents a good illustration of the importance of cleanliness of the body; for the symptoms are so benign that medical advice is rarely sought unless added disturbances supervene.

PIES AND CAKE FOREVER!

Pie is essentially an American dish. Until recently it shared, in certain quarters at least, the characteristic derogation that has often been directed at some of our national products and customs. Forgetting how our Yankee forefathers included pies as the veritable basis of their daily diet, the critics have sought to impugn this widely eaten American product and to assail its use. The dictionary has long defined pie as "prepared food baked either between two layers or crusts of pastry or with only an upper or lower layer." The almost infinite variety of combinations with fruits, meats and what not that the use of flour in the ready-to-eat form of pie permits has served greatly to enhance the popularity of the edible food. Of course there are pies and pies; yet the diversity of pastry cooks and their unlike talents scarcely warrants the unfortunate repute that pie has acquired in many quarters. Foremost is the charge of indigestibility; but why the combination of flour with fat and fruit should preferably be in the form of bread and butter with apple sauce or fruit jam rather than as delectable apple or strawberry pies is difficult to fathom. At any rate, the experts or "food specialists" seem to be showing a change of heart and a revision of ideas. Cake likewise seems to be coming into its own. A recent writer[2] has justly insisted that cakes are real foods. They should not be regarded solely as confections to tempt the jaded appetite, but for what they are—good sources of food essentials. To the charge that cakes are too "rich" for many persons, it should be noted that as a general average these products contain 1,500 calories to the pound, or only 25 per cent more than the average bread. If we translate a culinary blend of flour and eggs with butter, fruits or nuts into terms of foodstuffs, the answer indicates proteins, fats, carbohydrates, mineral nutrients and vitamins. A slice of bread and butter is almost twice as rich in fat as "gold cake" or "devil's food." The day of reckoning has arrived. American pies and cakes will survive the ordeal of dietary criticism.

SMALLPOX TAKES ITS TOLL

The way of the transgressor is admittedly hard; and it seems as though the efforts of the reformer also are sometimes beset with undeserved if not insurmountable difficulties. The crusade for the public health continually encounters the forces of ignorance, indifference, prejudice and self-interest that blindly resist innovation and progress. Occasionally it almost seems as though betterment of the race and increased happiness of the individual could be accomplished only at a sacrifice of human effort and self-respect that seems too exorbitant. The prevention of disease as it is practiced today is based on discoveries and experiences that have become a part of the permanent knowledge of the race. Success in preventive medicine therefore demands the unflagging inculcation of established facts. Sometimes this means rebuff and reiteration; but the end to be attained is, after all, precious enough to discount discouragements. Recently our news columns recorded[1] that 163 persons are known to have died of smallpox in California during the first quarter of the year. The cases reported numbered nearly two thousand. One hundred and thirty-six of these deaths occurred in one of the most enterprising cities of the world, Los Angeles. This heavy toll of human life is not attributable to any local impossibility of securing advantage of the triumphs of modern prevention of smallpox. It was not due to the incompetence of the medical profession. The real cause is to be found in the indifference or even active opposition engendered through the influx of antimedical forces. As truth is the best defender of the faith, no opportunity should be overlooked to make the records of history tell their story to those who may waver in their acceptance of the help of modern medicine or even sneer at its claims. In the Jubilee Volume of the American Public Health Association, Chapin[2] significantly records that during the last fifty years only one school child in Providence, R. I., has had smallpox, and that was one of the exceedingly small number of children who, for one reason or another, escaped vaccination. If vaccination were compulsory for all school children, the same record would prevail in all the schools throughout the United States. If some one were to say that the smallpox death toll in California is taken largely among adults, he may be referred to the records of the World War. Despite the extreme half of the samples tested the alcohol appears to have been derived wholly, or in part, from denatured alcohol.

SMALLPOX TAKES ITS TOLL

The way of the transgressor is admittedly hard; and it seems as though the efforts of the reformer also are sometimes beset with undeserved if not insurmountable difficulties. The crusade for the public health continually encounters the forces of ignorance, indifference, prejudice and self-interest that blindly resist innovation and progress. Occasionally it almost seems as though betterment of the race and increased happiness of the individual could be accomplished only at a sacrifice of human effort and self-respect that seems too exorbitant. The prevention of disease as it is practiced today is based on discoveries and experiences that have become a part of the permanent knowledge of the race. Success in preventive medicine therefore demands the unflagging inculcation of established facts. Sometimes this means rebuff and reiteration; but the end to be attained is, after all, precious enough to discount discouragements. Recently our news columns recorded[1] that 163 persons are known to have died of smallpox in California during the first quarter of the year. The cases reported numbered nearly two thousand. One hundred and thirty-six of these deaths occurred in one of the most enterprising cities of the world, Los Angeles. This heavy toll of human life is not attributable to any local impossibility of securing advantage of the triumphs of modern prevention of smallpox. It was not due to the incompetence of the medical profession. The real cause is to be found in the indifference or even active opposition engendered through the influx of antimedical forces. As truth is the best defender of the faith, no opportunity should be overlooked to make the records of history tell their story to those who may waver in their acceptance of the help of modern medicine or even sneer at its claims. In the Jubilee Volume of the American Public Health Association, Chapin[2] significantly records that during the last fifty years only one school child in Providence, R. I., has had smallpox, and that was one of the exceedingly small number of children who, for one reason or another, escaped vaccination. If vaccination were compulsory for all school children, the same record would prevail in all the schools throughout the United States. If some one were to say that the smallpox death toll in California is taken largely among adults, he may be referred to the records of the World War. Despite the extreme ease of transmitting contagion in great armies, this disease was a negligible factor in the mortality lists. Even among adults, therefore, almost perfect protection is secured against smallpox when vaccination and revaccination are universally followed. Smallpox must be made to vanish—even if such established platitudes must be reiterated again and again and again.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Summer Medical Courses.—The University of Alabama School of Medicine offers summer courses from June 2 to August 17 in anatomy, pharmacology, surgery and physiologic chemistry, which are of the same character as courses of the regular school session, and for which full credit is given. The classes are limited to forty students in each subject. While designed for medical students, the courses are open to others qualified, provided there are vacancies after medical students have registered. The second term of the summer session opens, July 14.

CONNECTICUT

Another Hospital Centennial.—The New Haven General Hospital, New Haven, celebrated the completion of its first hundred years of service to the community, May 27. In the morning, addresses were made by the heads of four departments of Yale University Medical School, which now conducts the hospital, and following a luncheon, Dr. William H. Carmalt, one of the oldest general practitioners of Connecticut, spoke on "A Retrospect of One Hundred Years," followed by Dr. Rufus I. Cole, Rockefeller Institute, New York, on "The Modern Hospital and Medical Progress." Among the speakers were Drs. Eugene M. Blake, Samuel C. Harvey, Arthur H. Morse and Edwards A. Park, all of Yale University Medical School. The celebration closed with a banquet at which President Angell of Yale, Mayor Tower of New Haven, and representatives of other hospitals in the city gave addresses.

GEORGIA

Society News.—Dr. Henry M. Fullilove, Athens, was elected president of the Railway Surgeons Association of Georgia at the seventy-seventh annual convention, May 11; Drs. Josephus J. P. Bowdoin, Atlanta, William M. Folks, Waycross, and Agnew H. Hilsman, Albany, vice presidents, and Dr. Jarrett W. Palmer, Ailey, secretary-treasurer.——Dr. Leland G. Baggett addressed the Fulton County Medical Society, Atlanta, May 20, on "Gastric and Duodenal Ulcers"; Dr. James K. Fancher gave a clinical talk on "Abnormal Body Weights and Their Relation to the Endocrines."——Drs. Edward S. Cowles and Burr Ferguson, both of New York, addressed a special meeting of the Fulton County Medical Society, Atlanta, June 2, on "Psychopathology with Special Reference to Medicine" and "Control of White Blood Cells," respectively.

IDAHO

Personal.—Dr. Ezra E. Fry, Bonners Ferry, has been elected president of the Bonner County Medical Society, and Dr. Nathaniel R. Wallentine, secretary-treasurer.——The governor has appointed Dr. John I. McKelway, former assistant superintendent of the Western State Hospital at Fort Steilacoom, Wash., as superintendent of the Northern Idaho Sanitarium at Orofino, to succeed Dr. John W. Givens.

ILLINOIS

Physician Sentenced.—Dr. John W. Ballance, Marion, formerly mayor of Harrisburg, Ill., has been sentenced to serve one year and one day in the federal penitentiary at Leavenworth, Kan., it is reported, for violation of the Harrison Narcotic Law.

State Medical Election.—At the seventy-sixth annual meeting of the Illinois State Medical Society, Champaign, May 20, Dr. Mather Pfeiffenberger, Alton, was elected president; Dr. Gustaff H. Mundt, Chicago, president elect; Drs. Earl D. Wise, Champaign, and Charles S. Nelson, Springfield, vice presidents; Dr. A. J. Markley, Belvidere, treasurer, and Dr. Harold M. Camp, Monmouth, secretary. The next annual meeting will be at Moline.

Down-State Milk Control.—The state department of health recently completed detailed inspections of the 349 down-state pasteurizing plants which furnish most of the milk consumed in cities, in accordance with a new law which requires that all pasteurizing plants, except those serving the city of Chicago, secure, annually, certificates of approval from the state health department. These were the first inspections preliminary to issuing certificates of approval. The state health director states that the municipal milk supplies this summer will be of a distinctly better sanitary quality than ever before.

Society News.—At the regular meeting of the Rock Island County Medical Society, Moline, May 11, it was unanimously voted to go on record against the bill recently introduced into the U. S. Senate (no. 4085) "to strengthen the Harrison Narcotic Act"; the scientific program at the meeting comprised addresses by Dr. Burton Hazeltine, Chicago, on "Bronchial Asthma"; Dr. Alvin W. La Forge, Chicago, "The Internist's Problem in Asthma," and Dr. Ralph Kuhns, Chicago.——Dr. Henry G. Schmidt has been elected president of the Elgin Physicians' Club, and Dr. Floyd A. Pingree, secretary-treasurer (reelected); the next meeting will be in October.

Chicago

Personal.—Dr. John Gordon Wilson has been elected chief of staff of the Wesley Memorial Hospital, to succeed the late Dr. William E. Schroeder.

Dedication of Memorial.—The John B. Murphy Memorial Association and the American College of Surgeons announce that the John B. Murphy Memorial building, 48 East Erie Street, Chicago, will be dedicated, June 10-11. Mr. L. A. Goddard, president of the Memorial Association, will preside, June 10, on which day, Sir Berkeley G. Moynihan will deliver an oration. Dr Rudolph Matas will preside, June 11, when addresses will be given by Dr. George W. Crile, Cleveland; Dr. William W. Chipman, Montreal, Canada, and Dr. William J. Mayo, Rochester, Minn.

INDIANA

Personal.—Dr. Dudley F. Davis has been elected president of the New Albany Academy of Medicine.——Dr. and Mrs. Barton S. Sheffer, St. Joe, celebrated their golden wedding anniversary, March 14.——Dr. Walter W. Lee has assumed his new duties as state epidemiologist for the state board of health, to succeed Dr. Arthur L. Oilar; Dr. Lee has been in practice at Winona, Ontario, Canada.

Cancer Clinic.—Dr. Joseph C. Bloodgood, Johns Hopkins University Medical School, Baltimore, conducted a cancer clinic at St. Margaret's Hospital, Hammond, May 13, for physicians of the Tenth Indiana Congressional District and others Dr. Bloodgood also addressed a community health meeting at the high school, which was a part of the program of "Civic Week"; other speakers at this meeting were Allen Craig, Chicago, and Father C. B. Moulinier, Milwaukee, president of the Catholic Hospital Association.

IOWA

State Medical Election.—At the annual meeting of the Iowa State Medical Association, Des Moines, Dr. Thomas E. Powers, Clarinda, was elected president; Dr. Michael J. Kenefick, Algona, president elect; Dr. Frederick G. Murray, Cedar Rapids, vice president; Dr. Addison C. Page, treasurer, and Dr. Tom B. Throckmorton, Des Moines, secretary. The next annual meeting will be at Council Bluffs. The association adopted a new plan of conducting business, vesting authority in a board of trustees of three members, to which the house of delegates elected Dr. Vernon L. Treynor, Council Bluffs; Dr. Oliver J. Fay, Des Moines, and Dr. John F. Herrick, Ottumwa, all past presidents of the association.

KENTUCKY

Narcotic Violation.—Dr. William A. Francis, Bowling Green, pleaded guilty, May 18, to violating the Harrison Narcotic Act, it is reported, and was sentenced to one year in jail and to pay a fine of $1,000. The jail sentence, it is said, was suspended.

Hospital News.—The Kosair Convalescent Home for Crippled Children, representing an expenditure of about $200,000, contributed by the public, was formally opened, May 13; white crippled children under 12 years of age, of any creed, are eligible for admission to the home. The Masonic Order will have general supervision over the home.

Society News.—Dr. Adolph O. Pfingst has been elected president of the Louisville Eye and Ear Society for 1926; Dr. Melvin C. Baker vice president, and Dr. Charles C. Maupin, secretary-treasurer.——Dr. John F. Dunn, Arlington, was recently elected president of the Southwestern Kentucky Medical Association; Drs. Claude E. Kidd, Paducah, and George W. Payne, Bardwell, vice presidents, and Drs. James Vernon Pace and James T. Reddick, both of Paducah, secretary and treasurer, respectively; the semiannual meeting in October will be held in Murray.——Dr. Arthur T. McCormack, Louisville, has been reelected president of the Kentucky Conference on Social Work.——Dr. William R. Burr, Auburn, has been elected president of the Third District Medical Society to succeed Dr. Carl C. Howard, Glasgow.

MARYLAND

Arrests for Not Reporting Births.—The state board of health has recommended the prosecution of fifteen physicians in the state and four midwives for failure to report births in accordance with the state law. The announcement was made following the completion of a survey designed to ascertain the efficiency of birth reporting in the state.

Society News.—The Medical Society of the District of Columbia and the Baltimore City Medical Society held a joint meeting in Baltimore, recently, which was addressed by Dr. Charles S. White on "The Unsatisfactory Side of Gallbladder Surgery" and by Dr. Roy D. Adams on "The Ex-Service Man as a Problem in Diagnosis."——The Maryland Psychiatric Society and the Washington Society for Nervous and Mental Diseases held a joint meeting, May 20, at the Chestnut Lodge Sanatorium, Rockville, which was addressed by Dr. William A. White, superintendent, St. Elizabeth's Hospital, Washington, D. C., on "The Language of Schizophrenia."——Dr. Esther L. Richards, Johns Hopkins Hospital, addressed the Baltimore County Medical Society, May 19, at Harlem Lodge, Catonsville, on "Psychologic Aspects of Child Welfare."——Among others, Dr. Martin F. Sloan addressed the West Baltimore Medical Society, May 19, at the West Baltimore General Hospital on "Interesting Pulmonary Symptoms Simulating Tuberculosis."

Johns Hopkins' Fiftieth Anniversary.—Invitations have been sent to 12,000 former students for the fiftieth anniversary of the founding of Johns Hopkins University, October 22-23. The chief event will be the dedication of the new $1,000,000 building of the School of Hygiene and Public Health; Dr. Andrew Balfour, director, London School of Hygiene and Tropical Medicine, will speak at the dedication, and Prof. F. Neufeld, Berlin, director, Institute for Infectious Diseases, will deliver the De Lamar memorial lecture. The governor, Albert C. Ritchie, an alumnus of the university, has appointed a committee of thirty-seven citizens to represent the state at the celebration, and the mayor of Baltimore, a committee of 220 to represent that city. Among other prominent speakers at the functions will be Dr. Ira Remsen, second president of the university and the only surviving member of the original faculty of seven professors; Newton T. Baker, former secretary of war; Dr. Charles R. Bardeen, dean and professor of anatomy, University of Wisconsin Medical School, and Daniel Willard, president, Baltimore and Ohio Railroad and president of the board of trustees of Johns Hopkins University.

MASSACHUSETTS

Dr. Faxon Honored.—About 125 associates and friends of Dr. William O. Faxon, Stoughton, tendered him a complimentary dinner, May 1, in recognition of his public service in Massachusetts and his completion of fifty years in the practice of medicine.

Senate Disapproves Lye Bill.—The bill designed to prevent suffering by means of labeling in a specific manner all caustic or corrosive substances offered for sale was voted down by the Massachusetts state senate, although approved, says the *Boston Medical and Surgical Journal*, by the house. The bill had also been approved by the joint committee on legislation of the medical societies and the committee of the legislature had been so informed. The primary intent of this legislation, the like of which has been passed by many other states, is to prevent the suffering and disability that occurs among children who innocently swallow caustic and corrosive household substances. The Boston editor therefore says about the senate's action: "We wish to go on record that such behavior of a representative body is beyond the comprehension of physicians, who, having no selfish motives, are asking for the cooperation of our lawmakers in efforts to protect the public."

MICHIGAN

Personal.—Dr. Franklin W. Sassaman has been reappointed health officer of the city of Charlotte, making this his seventeenth year of continuous service.——Dr. Starr K. Church has been reelected city health officer of Marshall.——Dr. S. Rowland Hill has been reelected city health director of Lansing for the sixth time.

Clinics for Crippled Children.—During 1925 the Michigan Society for Crippled Children arranged for clinics at which 1,504 crippled children from seventeen different counties were in attendance. The greatest number of children examined by any one clinic was 142 in Houghton County; then 132 at Kalamazoo; 117 at Alpena; 116 at Cadillac, and 114 at Oakland. The society's clinic at Jackson has employed a public health nurse to direct the work, and some of the other large clinics have employed assistants.

Child Health Institute.—The Detroit Department of Health, cooperating with the board of education and other organizations, will hold the first annual child health institute in Detroit, on the twelfth floor of the Hudson Store, the week of June 7; there will be demonstrations of the health work done in the city public schools and lectures daily on prenatal care, infant care, behavior problems, health habits and recreation, and on Friday evening an address by Dr. Hugo A. Freund on "Adding Years to the Average Life."

Society News.—Dr. Martin A. Mortensen, Battle Creek, addressed the Wayne County Medical Society, Detroit, May 18.——Members of the Wayne County Medical Society were invited to attend the annual meeting of the Detroit Dermatological Society at Harper Hospital, May 25.——Dr. William B. Bartlett, Boston, addressed the Berrien County Medical Society, Benton Harbor, April 26, on "Treatment of Diabetes Mellitus in Children," and demonstrated the modern methods of taking basal metabolic rate determinations.——Members of twelve county medical societies in Michigan have agreed to undergo a periodic physical examination; one week after the matter had been presented to the St. Clair County Medical Society, all of its members had been examined.——Dr. Elmer L. Eggleston, chief, medical service, Battle Creek Sanitarium, addressed the Kent County Medical Society, May 26, on "Periodic Physical Examinations."

MISSOURI

License Revoked.—The Missouri State Board of Health, May 6, revoked the license of Dr. William H. Duckworth, St. Clair, it is reported, on a charge of unprofessional conduct. Dr. Duckworth is said to have been indicted by the March grand jury of Franklin County on a charge of having performed an illegal operation.

Largest Medical Reserve Officers' Training Corps.—St. Louis University Schools of Medicine and Dentistry have, according to the *Globe Democrat*, the largest reserve officers' training corps among the medical and dental schools of the United States, the total enrolment being 583. At the commencement in June, 102 members of the graduating classes in medicine and dentistry will be commissioned by the President as first lieutenants in the officers' training corps.

State Medical Election.—At the sixty-ninth annual meeting of the Missouri State Medical Association, St. Louis, May 17-20, Dr. Emmett P. North delivered the presidential address at a general meeting, Wednesday evening; Dr. Jabez N. Jackson, Kansas City, President-Elect of the American Medical Association, and Dr. John A. Witherspoon, Nashville, Tenn., also gave addresses; Dr. Francis Park Lewis, Buffalo, gave an address on "Achievements in the Prevention of Blindness"; Dr. Witherspoon also held a diagnostic clinic, Thursday afternoon, on duodenal and gastric ulcer. The meetings were all held in the auditorium at St. Louis University, except the clinics. The following officers were elected: Dr. William H. Breuer, St. James, president; Drs. George C. Willson, Nevada, Ross A. Woolsey, St. Louis, Francis M. McCallum, Kansas City, Paul F. Cole, Springfield, and Uriel P. Haw, Benton, vice presidents; Dr. George W. Hawkins, Salisbury, treasurer, reelected, and Dr. Edward J. Goodwin, St. Louis, secretary-editor, reelected. The next annual meeting will be at Sedalia.

Personal.—Dr. William L. Bradford, Sedalia, has been elected president of the Missouri Public Health Association; Dr. Elbert L. Spence, Kennett, vice president, and Dr. James Stewart, secretary of the state board of health, secretary.——Dr. Howard M. Smith, Kansas City, has been appointed head of the old City Hospital.——Dr. Porter E. Williams, Boonville, assumed the duties of superintendent of the General Hospital, Kansas City, April 14; Dr. Williams for years has been superintendent at various state hospitals.——Dr. Jule H. Keller, Lancaster, has been elected president of the Schuyler County Medical Society, and Dr. James B. Bridges, Downing, secretary, reelected.——Dr. Evarts A. Graham, Bixby professor of surgery, Washington University School of Medicine, succeeds the late Dr. Albert J. Ochsner, Chicago, as editor of the Year Book of General Surgery of the Practical Medicine Series.——Dr. Isaac N. Parrish Cowgill, has been appointed physician to the Indian schools at Colony, Okla., and has moved to that city.——Dr. Jabez N. Jackson, Kansas City, President-Elect of the American Medical Association, received the honorary degree of doctor of science from Park College at the recent commencement exercises.

NEBRASKA

Hospital News.—Dr. Charles E. Slagle, Alliance, was elected president of the medical staff of St. Joseph's Hospital at the annual meeting, May 7.——The Lanning Memorial Hospital, Hastings, has let the contract for construction of a $75,000 maternity unit.

Personal.—Dr. Frank L. Frink, Newman Grove, has been elected mayor for the third consecutive time.——Dr. Arno A. Bald, Platte Center, has been reappointed county physician of Platte County.——Dr. Russell J. Murdoch has been reelected mayor of Blair.——Dr. Clement L. Martin, Omaha, has become a member of the permanent staff of the Mayo Clinic, Rochester, Minn.——Dr. Ethel M. Laybourne has been appointed superintendent of the Bryan Memorial Hospital, Lincoln.

Society News.—The Nebraska Association of Medical Directors, representing twelve insurance companies, was organized, May 12, at Omaha, with Dr. Albert R. Mitchell, Lincoln, president; Dr. Arthur C. Stokes, Omaha, vice president, and Dr. Reuben A. Moser, Omaha, secretary-treasurer.——Dr. May L. Flanagan, Lincoln, was elected president of the Nebraska Association of Medical Women, May 11, at Omaha; Dr. Charlotte P. Seiver, Fremont, vice president, and Dr. Ruth A. Warner, Lincoln, secretary-treasurer.

NEW YORK

Personal.—Dr. Clarence Floyd Haviland, Albany, has resigned as chairman of the state hospital commission to become superintendent of the Manhattan State Hospital at Wards Island, July 1, and Dr. Frederick W. Parsons, superintendent of the Buffalo State Hospital, has been appointed to succeed Dr. Haviland as chairman of the state hospital commission.——Drs. Moses Keschner and Israel S. Wechsler have been appointed attending neurologists to the Montefiore Hospital, New York.——Dr. Ezra R. Bridge has been appointed superintendent of the Monroe County Sanatorium, Rochester.

Progress in Rehabilitating State Hospitals.—Governor Alfred E. Smith has issued a pictorial pamphlet to show the progress in rehabilitating the state hospitals and charitable institutions, and what is being done with the $50,000,000 bond issue which the people authorized at the 1923 election. There is a picture of additions to the Hospital for Crippled Children at West Haverstraw which will provide for 200 patients and sixty employees; another of the Harlem Valley Hospital, where some buildings are already occupied and where these bonds will provide 1,204 new patients' beds. Additions to Letchworth Village will provide 400 additional patients' beds for the infirm female inhabitants; a new hospital for sick inmates, a new administration building and new homes for attendants are under construction. There is a picture of the Creedmoor State Hospital for the Insane where buildings have already been erected and others are under construction; which will provide 1,044 additional patients' beds and relieve the overcrowding at Brooklyn State Hospital. There is a drawing of an entirely new hospital to be built in Rockland County, which will provide 3,800 beds and cost about $10,000,000. During 1924 and 1925 there have been added 8,066 new beds for patients in state institutions. The governor says that state officials are carrying on this great program with all possible energy; that the entire plan, only a part of which is shown in this pamphlet, has been carefully considered, and that it would have been impossible to lay out any such building program had there not been the assurance that funds would be available each year. From these studies of the hospital situation, the needs of the state in beds up to the year 1935 have been determined; the state can now say how large an institution ought to be and where it ought to be. Less than half of the $50,000,000 bond issue, as yet, has been expended.

New York City

Fifteen Chiropractors in Court.—Fifteen chiropractors were arraigned in Chief Magistrate McAdoo's Court, April 13, on charges of violating the "health law"; each was released on $500 bail. The charges were made by policewomen of the city to whom the chiropractors are said to have administered treatment recently.

Steel Work at Medical Center Completed.—Gen. William Barclay Parsons, chairman of the Joint Administrative Board for the $11,000,000 structure which will house the Presbyterian Hospital and the College of Physicians and Surgeons at Broadway and One Hundred and Sixty-Eighth Street, had the honor, May 24, of driving the last rivet in the steel framework of the building.

Society News.—Dr. Ralph Pemberton, Philadelphia, took part in a symposium on arthritis before the Medical Society of the County of New York at the Academy of Medicine, May 24; Dr. Pemberton's subject was "Significance and Use of Dietetics in the Treatment of Arthritis."——Dr. Joseph F. Ward has been nominated president for the coming year of the Brooklyn Society of Internal Medicine, and Dr. Joseph G. Terrence, secretary.——At the annual meeting of the Women's Medical Association, May 12, at the Women's City Club, Dr. Eleanor Vanness, Van Alstyne was elected president; Drs. Mary A. Reesor and Sophie Rabinoff, vice presidents; Dr. Allis Hascall, treasurer; Dr. Isabelle Beck, recording secretary, and Dr. Elsie A. Barthel, corresponding secretary.

Hospital News.—Two new departments will be added to the dispensary of the Knickerbocker Hospital on completion of its new $500,000 emergency unit next fall; they will be a prenatal clinic and a nose and throat clinic.——Raquel Meller, Spanish singer and dancer, gave a special performance recently to aid the St. Mary's Free Hospital for Children.——St. Peter's Hospital, Brooklyn, has purchased the adjoining building of the home for the aged, and a new wing will be built on the site.——The staff of the new maternity department of the Knickerbocker Hospital includes Dr. George L. Brodhead, visiting obstetrician; Drs. Edwin G. Langrock and Ralph Barrett, associate obstetricians, and Drs. Walter T. Stenson and Donald M. Campbell, assistant obstetricians.——The Hospital for Joint Diseases formally dedicated its country home at Far Rockaway, May 16. This mansion, representing a gift, including its endowment of $1,100,000, by Alfred Heinsheimer, has been rearranged to accommodate 100 patients; it stands on 14 acres of ground at Breezy Point.——The Memorial Hospital, Central Park West at One Hundred and Fifth Street, celebrated the completion of a new wing, May 12.

OHIO

Report of Military Committee.—The annual report of the military committee of the Ohio State Medical Association shows that there are 447 physicians commissioned in the medical reserve corps, and 195 dentists, of whom 71 and 24, respectively, were commissioned during 1925. The report says that 3,000 Ohio physicians, or about 70 per cent of the membership of the state medical association, served during the World War, and that during the Civil War 10 per cent of the entire membership of the Ohio State Medical Association was killed in action. Applications are needed to complete the general mobilization plans formulated by the general staff of the war department.

Society News.—Dr. Robert B. Cofield, associate professor of orth [illegible] y, University of Cincinnati School of [illegible] larence A. Mills, assistant professor of [illegible] of Cincinnati College of Medicine, addressed the Drake County Medical Society, May 8, on "Cause and Treatment of Back Pains" and "Significance and Methods of Treatment of Hemorrhages."——Dr. Charles F. Hoover, professor of medicine, Western Reserve University School of Medicine, Cleveland, addressed the Summit County Medical Society, Akron, May 18, on "Bedside Observation on Respiration."——Dr. Howard M. Clute, Boston, addressed the members of the Academy of Medicine of Toledo and Lucas County, May 7.——The Academy of Medicine of Toledo and Lucas County announced a course of lectures on "The Heart" to be given June 1-5, by Dr. Frank N. Wilson, University of Michigan Medical School, Ann Arbor.

OKLAHOMA

Personal.—Dr. Laurence H. Carleton, formerly of Tulsa, has accepted an appointment at the Henry Ford Hospital, Detroit. ——Dr. Ira C. Wolfe has been appointed city physician of Muskogee to succeed Dr. Charles E. White, resigned.—— Dr. Finis E. Sadler has been appointed city physician of Henryetta.——Dr. William E. Floyd has been appointed city superintendent of health of Muskogee.

Society News.—The Muskogee County Medical Society held an open meeting recently at the Presbyterian Church, Muskogee, conforming to the plans of the publicity committee of the state association. The church was crowded with laymen and physicians. Dr. LeRoy Long, dean, University of Oklahoma School of Medicine, gave an address on "The Relations of Scientific Medicine to the Community."

PENNSYLVANIA

Everyday Problems in Medicine.—Dr. Thomas McCrae, Magee professor of the practice of medicine and clinical medicine, Jefferson Medical College, Philadelphia, will address the physicians of seven counties of northwestern Pennsylvania at Warren, June 21, on "Everyday Problems in Medicine."

Personal.—Dr. Julian Ellis Kurtz, who recently retired from practice of medicine, has donated to the Berks County Medical Society 400 volumes, mostly on subjects related to diseases of the eye, ear, nose and throat. Dr. Kurtz is said to have been a member of the society since his graduation from Jefferson Medical College in 1880.

Hospital News.—A campaign to raise $6,000,000 will be undertaken soon for the purpose of increasing the Presbyterian Hospital, Pittsburgh, from a 150 bed institution to a 600 bed unit in the Pittsburgh Medical Hospital group.—— Providence Hospital, New Brighton, is conducting a campaign for $250,000.——St. Christopher's Hospital for Children, Philadelphia, recently established a neuropsychiatric clinic in connection with the department of preventive medicine; the staff of the new clinic consists of Dr. James J. Waygood, psychiatrist, Esther K. Rosen, Ph.D., psychologist, Edwin Westburgh, psychologist, and Fannie E. Teller, psychiatric social worker.

Philadelphia

Bequest to Jefferson Medical College.—The late William Potter, president of Jefferson Medical College and Hospital, bequeathed $50,000 in his will to Jefferson Medical College.

University News.—Dr. Lillian K. P. Farrar, New York, will address the Alumni Association of the Women's Medical College of Pennsylvania at the seventy-sixth anniversary of the college, June 10-11, on "Reaction of Tissues to Radium Treatment in Cancer of the Cervix and the Importance of Lacerations in This Location."

Hospital News.—Rush Hospital for Consumptives opened a new ward for advanced cases, May 27, which was presented by Charles P. Hall, president of the city council, in memory of his wife, who died twenty-five years ago.——The drive for $1,000,000 to build an addition to the Bryn Mawr Hospital was opened, June 2, with a dinner at the Bellevue-Stratford; more than 600 persons were present; Samuel Rea, chairman, executive committee in charge of the drive, presided. The drive will close, June 11.

Periodic Health Examinations.—Our correspondent writes that the long-awaited joint drive of the medical profession and the laity against cancer, nephritis and preventable diseases opened at a public meeting at the new Philadelphia County Medical Society Building, June 1, which was presided over by Mr. Alba B. Johnson, the new president of Jefferson Medical College; among the speakers were Dr. Orlando H. Petty, chairman, committee on periodic health examinations, Philadelphia County Medical Society; Dr. John Norman Henry, past president of the state medical society, and Dr. Harry Toulmin.

Navy Program.—The Medical Department of the U. S. Navy presented the entire program for the May 26 meeting of the Philadelphia County Medical Society, Capt. Arthur W. Dunbar, assistant surgeon general, representing Admiral E. R. Stitt, who was absent on account of illness. Among others who took part in the program were Lieut. Comdr. Walter A. Bloedorn, whose subject was "Periodic Health Examinations," and Capt. Richmond C. Holcomb, who gave an illustrated lecture on "Medical Officers Afloat." Other speakers were Capts, George T. Smith and James F. Leys, and Lieut. Comdrs. Abraham H. Allen, Joseph J. A. McMullin, Carrol R. Baker, George A. Eckert and John M. McCombs. Members of the reserve corps of the army and navy were requested to attend the meeting in uniform.

SOUTH DAKOTA

State Medical Election.—At the annual meeting of the South Dakota State Medical Association, Aberdeen, May 19-20, Dr. Theodore F. Riggs, Pierre, was elected president; Drs. Silas M. Hohf, Yankton, Nelson K. Hopkins, Arlington, and Lorenzo N. Grosvenor, Huron, vice presidents, and Dr. John F. D. Cook, Langford, secretary-treasurer.

Personal.—Dr. Francis E. Clough, Lead, has been appointed a member of the state board of health and medical examiners to succeed the late Dr. John W. Freeman, Lead.——Dr. William F. Keller, who has been connected with the board of health of Sioux Falls for nineteen years, has resigned, and Dr. T. J. Billion has been elected to fill the vacancy.——Dr. George M. Boteler, health officer of the board of health of Aberdeen for several years, has resigned, and will engage in practice in St. Louis.

TEXAS

University News.—The University of Texas has reorganized its department of botany to provide for the development of courses in bacteriology, and changed its name to the department of botany and bacteriology; I. M. Lewis, Ph.D., is the professor of bacteriology.

Personal.—Dr. Richard McCormick, Waco, has been reappointed county health officer for two years.——Dr. C. W. Gray, Brownwood, has been appointed county health officer to succeed Dr. Thomas B. Bailey, who recently resigned to become the city health officer of Brownwood.——Dr. Alfred L. Ridings has been appointed city health officer of Sherman, to succeed the late Dr. James A. Swafford.——Dr. Herschel F. Connally has been elected mayor of Waco.

State Medical Election.—At the annual meeting of the Texas State Medical Association, Houston, May 24-27, Dr. William Keiller, Galveston, was elected president; Dr. Joseph Gilbert, Austin, president-elect; Drs. Calvin R. Hannah, Dallas, Malone Duggan, Laferia, and James Greenwood, Houston, vice presidents, and Dr. Holman Taylor, Fort Worth, secretary. The campaign of publicity and law enforcement which is being conducted by the state medical association was enthusiastically endorsed at this meeting and ordered to be continued with vigor. The next meeting will be held at El Paso.

VIRGINIA

Society News. — Dr. Claude C. Coleman, Richmond, addressed a joint meeting of the Warwick County Medical Society and the Peninsula Dental Society at Newport News, May 10, on "Facial Pain."——Dr. Edward Howe Miller, Jr., Danville, has been elected president of the South Piedmont Medical Society, and Dr. George A. Stover, South Boston, secretary-treasurer, reelected.——At the annual meeting of the Virginia Society of Otolaryngology and Ophthalmology, Charlottesville, April 27, Dr. Clifton M. Miller, Richmond, was elected president; Dr. Charles S. Dodd, Petersburg, vice president, and Dr. Fletcher D. Woodward, Charlottesville, secretary-treasurer.——The Medical Association of the Valley of Virginia met in Harrisonburg, May 27; among others, Dr. Hugh H. Young, Baltimore, gave an address.——At the annual meeting of the Walter Reed Medical Society, Yorktown, May 21, Dr. John W. C. Jones, Newport News, was elected president; Dr. John M. Henderson, Williamsburg, first vice president; Dr. James E. Marable, Newport News, treasurer, and Dr. Landon E. Stubbs, Newport News, secretary; on the second day, the members went to Fort Eustis to see demonstrations in the treatment of fractures, then returned to Yorktown, and were addressed by Dr. Southgate Leigh, Norfolk, on "The Importance of Periodic Medical Examinations," and by Dr. William Wayne Babcock, Philadelphia, on "Surgery in Relation to Gallbladder Diseases."

WEST VIRGINIA

Personal.—Dr. David Berman has been appointed health officer of Marshall County; Dr. Berman was formerly instructor in public health and hygiene at Antioch College, Antioch, Ohio.——The governor has appointed Dr. Mortimer D. Cure, Weston, superintendent of the Weston State Hospital.——Dr. John W. Niedermeyer has been appointed city health officer of Benwood, succeeding Dr. William B. Hartwig, resigned.

Society News—Dr William T Henshaw, state commissioner of health, addressed the Kenawha County Medical Society, recently, on illegal practitioners in West Virginia ——Dr Thomas R Boggs, assistant professor of medicine, Johns Hopkins Hospital, Baltimore, addressed the Academy of Medicine of Parkersburg, recently, on "Biliary Disease" ——The Webster-Nicholas Medical Society has been reorganized so as to include physicians of Braxton County and named the Central West Virginia Medical Society, Dr. Charles Frederick Fisher, Richwood, was elected president, and Dr Homer S Brown, of Sutton, secretary-treasurer

HAWAII

Personal—Dr George S Bliss has resigned as superintendent of the Waimano Home, Hawaii, to accept a position as superintendent of the Pacific Colony, a new institution for the feebleminded at Spadra, Southern California

Annual Health Report—The death rate in Hawaii for the year ending June 30, 1925, a report of which has just been received, was the lowest in the history of the territory, 12 74 per thousand, the infant mortality rate was 103 59 per thousand, also the lowest on record The board of health credits this record to the work of the public health nurses in the districts, to the work of the Palama Settlement in the city of Honolulu, and to the inauguration of clinics for mothers and children by physicians and nurses on many plantations There were no cases of smallpox in the territory during the year, and only two cases of human plague, both of which were fatal, and fourteen cases of rodent plague In the plague eradication campaign, 176,593 rodents were obtained, and of these 169,826 were examined microscopically for plague The principal public health problem was brought about by a strike of the Filipino laborers, there was a number of deaths due to a lack of proper food and housing and overcrowding following the strike, but the strikers' camps were carefully inspected and a typhoid epidemic was averted.

GENERAL

National Association for Study of Epilepsy.—The twenty-fifth annual meeting of this association will be held at the Waldorf-Astoria New York, June 7 8, under the presidency of Dr George Kirby Collier, Rochester, N Y , among others, Drs Stanley Cobb and William G Lennox, Harvard Medical School, Boston, will discuss "Some Clinical and Laboratory Observations with Reference to Convulsions", Dr Leland B Alford, St Louis, "The Epileptic Convulsion Considered as a Type of Extrapyramidal Disturbance", Dr Smith E Jelliffe, New York, "Narcolepsy, Hypnolepsy, Pyknolepsy,' and Dr Otto Wuth, Johns Hopkins University Medical Department, "Rational Bromide Treatment—A New Method for Its Control' In the same program is announced the eighty-second annual meeting of the American Psychiatric Association at the Waldorf-Astoria, June 8-11

Medical Library Association.—The twenty-ninth annual meeting of this association will be held at Ann Arbor, Mich , June 7-9 Dr Hugh Cabot, dean, University of Michigan Medical School, will give the opening address, and Dr Frederick Tice, Chicago, president of the Medical Library Association, will give the response Among others, the librarian of the University of Michigan, Mr William W Bishop, will speak on 'The Present Status of International Bibliography in the Field of Science" There will be a reception, Tuesday evening, at the William L Clements Library, when Dr Aldred S Warthin, director, pathologic laboratory, University of Michigan, will demonstrate some unusual features in the Lewis Stephen Philcher collection of rare and early books in medicine, which collection will be on exhibition in the library The business meeting will be Tuesday afternoon

Prize Contest in Physical Therapy.—The American College of Physical Therapy announces a contest open to physicians physicists and fourth and fifth year students in recognized medical schools in which the six prizes will be physical therapy equipment, totaling a value of more than $2,500 The thesis, which must concern some branch of physical therapeutics, must not exceed 2,000 words and must involve some problem of research, and be typewritten, and double-spaced on one side of the paper only Theses must be submitted to the chairman of the committee, Dr Disraeli W Kobak, 30 North Michigan Avenue, not later than October 15 The winners will be announced at the Clinical Congress at the Drake Hotel, Chicago, October 18-23 The judges will be selected from the faculties of several medical schools, and will not be connected with the American College of Physical Therapy.

International Conference on Oil Pollution of Waters.—The state department announces that former Senator Joseph S Frelinghuysen of New Jersey will head the American delegation to the International Conference of Experts on Oil Pollution of Navigable Waters, which meets in Washington, June 8 Congress, in 1922, authorized the President to call a conference of maritime nations with a view to the adoption of effective means for the prevention of pollution of navigable waters The use of oil as fuel by vessels and the evils that result, including pollution of bathing beaches, harbors and shore property, and the consequent detriment to property and health, shore recreation, increased fire hazard and injury to the fishing industry and wild life, will be discussed It is hoped that the forthcoming conference may prepare plans for an agreement of maritime nations to control oil pollution The following countries have indicated their acceptance of invitations to attend the conference Belgium, Denmark, France, Germany, Great Britain, Greece, Italy, Japan, Netherlands, Norway, Spain and Sweden

Society News—At the meeting of the American Gynecological Society, May 20-22, Dr Arthur H Curtis Chicago, was elected president, Drs Frank W Lynch, San Francisco, and J R Goodall, Montreal, vice presidents, Dr Fred L Adair, Minneapolis, treasurer, and Dr Floyd E Keene, Philadelphia secretary ——Mrs E P Gengenbach Denver, was installed as president of the Women's Auxiliary of the American Medical Association at the recent annual meeting in Dallas, Texas, Mrs John O McReynolds, Dallas, was elected president elect ——At the annual meeting of the American Roentgen-Ray Society, Detroit, May 18-22, Dr Alexander H Pirie, Toronto, was elected president elect, Dr Patrick F Butler Boston, and Edward L Jenkinson, Chicago, vice presidents, Dr William A Evans, Detroit, treasurer, and Dr Charles L Martin, Dallas, Texas, secretary ——At the eleventh annual convention, Philadelphia, May 25 of the American Association of Industrial Physicians and Surgeons, Dr William A Sawyer of the Eastman Kodak Company, Rochester, N Y , was elected president, Dr Clare F N Schram, of the Fairbanks-Morse Company, Beloit, Wis , and Dr Robert S Quimby of the Hood Rubber Company, Watertown, Mass , vice presidents and Dr Frank L Rector, editor, *Nation's Health,* Chicago, secretary-treasurer (reelected)

Opposition to Strengthening Narcotic Law.—At a hearing held by the Ways and Means Subcommittee of the House of Representatives, May 24, vigorous opposition was made to the Treasury Department bill to strengthen the Harrison Narcotic Law by the American Pharmaceutical Association, represented by Samuel L Hilton, Washington, D C, and by the American Medical Association, represented by Dr W C Woodward Chicago Mr. Hilton sharply criticized the proposed provision which would require pharmacists to determine whether a physician's prescription was or was not issued in the course of professional practice and to refuse to fill such prescriptions as the pharmacist may reasonably suspect of not having been so issued He said, "Why should the druggist be jailed for following orders?' He opposed the provision for keeping records—additional to those now required—because it would increase the cost of drugs to the people he asserted that it would take from three to six hours to find out whether the ordinary prescription is lawful "If this requirement is enacted into law,' Mr Hilton said, "I shall surrender my narcotic license as a wholesaler I would decline absolutely to fill such a prescription and run a chance of violating the law The keeping of records has gotten to be a bugaboo for the druggists I spend three days out of the month in keeping my records The extra help needed to keep the proposed record would not be justified by the business" Dr Woodward, representing the American Medical Association, stated that further regulation of the narcotic traffic by the federal government would jeopardize the present antinarcotic laws, and that the determination of who may practice medicine and who may dispense drugs belongs to the states "But that does not leave Congress helpless,' Dr Woodward said "It can cooperate with the states At present there are twenty-nine states and three territories which have specific regulations authorizing the revocation of licenses of physicians known to be drug addicts We doctors approve of regulation through ordinary channels, through the states as at present, but we regard the proposed legislation as unwise" "With respect to this refusal of registration to doctors known as drug addicts," Dr Woodward continued, "the question arises, What is a drug addict, and how is that to be determined? The same penalty for a violation by a narcotic pedler would be laid on a physician who commits a minor infraction of the law, to wit, for forgetting to renew his license for a few days after it expired, and writing a prescription in that period. He would lose his practice for a year. Such a regulation would be a club held over the heads of doctors to compel them to compromise cases instead of defending themselves in court. If a trivial charge was placed against a doctor, he would readily compromise rather than run the chance of having his reputation questioned by an appearance in court on the charge of violating the Harrison act."

Dr. Woodward completed his testimony with a statement that the bill would not reach narcotic pedlers, and with a recommendation for a greater activity by the states in enacting narcotic laws directed at the addict. Horace W. Bigelow, Detroit, counsel for the American Drug Manufacturers' Association, and for Parke, Davis and Company, opposed the bill from the practical view of the manufacturer. He asserted that the expense of record keeping was enormous. "I think I can safely say," he said, "that our record keeping amounts to more than $100,000 a year. Now this bill would force us to duplicate the very records we are keeping. When we keep a record of sales to our various distributors, that record is also one of purchases for them. The bill would make us keep another record of purchases at an additional cost of perhaps $25,000 a year."

LATIN AMERICA

Next Latin American Medical Congress.—The official notice of the seventh Latin American Medical Congress has been issued, the date, March 15, 1927, at the City of Mexico. Dr. Angel Brioso Vasconcelos is secretary of the executive committee.

Personal.—Dr. G. Aráoz Alfaro, chief of the public health service of Argentina, has sailed for Europe as the representative of Argentina in the League of Nations' international health conference and the international public health office at Paris. ——*The Brazil-Medico* relates that Dr. Carlos Chagas, chief of the public health service of Brazil, has been notified that an honorary degree is to be conferred on him by the University of Paris at its convocation exercises in November.——The *Folha Medica* of Rio de Janeiro announces the arrival there of Drs. Allen Freeman and James Doull, who have been invited to deliver a course of lectures in the newly founded school of public health, as masters of sanitary administration.——The Academia Nacional de Medicina of Mexico has elected to honorary membership Dr. F. Lagrange, professor of ophthalmology, Bordeaux.——Dr. Ramón Goya of the Argentine cruiser *Buenos Aires* was tendered a banquet recently by the local medical society of Seville, Spain.——Dr. Varela Zequeira has been elected president of the national Cuban Medical Association to fill the vacancy left by the death of Dr. Juan Guiteras, who was the first president of the newly organized association. Its official title is the Federación Médica de Cuba. Dr. A. A. Aballi is president of the executive committee. The *Crónica Médico-Quirúrgica* for January is entirely devoted to the new organization, its aims and history to date.

FOREIGN

China Medical Association.—The eighteenth biennial meeting of the China Medical Association will be held at Peking, August 31-September 8, in the buildings of the Peking Union Medical College. A preliminary announcement from the chairman of the publicity committee states that the background and "motif" of the meeting will be public health, to which subject many of the general and public meetings will be devoted. The mornings will be devoted to sectional and general meetings; the afternoons to demonstrations and clinics, and the evenings to public lectures. A trip to the Great Wall of China has been arranged for the day following the conference and to other interesting places.

The German Health Week.—Extensive preparations were made for the national Health Week and exposition in Germany in April. Our exchanges state that hundreds of thousands of persons were reached by the health propaganda through the press or radio or moving pictures. Lay members of parliament expressed publicly their appreciation of the efforts of the profession to enlighten the public in matters of health. Gollwitzer of Munich, in particular, emphasized the necessity for eradicating quackery, but the *Deutsche medizinische Wochenschrift* calls attention to the way in which quackery—"radium compresses," etc.—crowded into the limelight even in the hygiene exhibition. The exhibits portraying the evils of alcohol and tobacco were stationed in the gallery above, while on the main floor booths for sale of both were attractively arranged. The government of Saxony is offering prizes to children for articles on "What the Health Week Brought to Me."

International Congress of Sexology.—The International Society of Sexology announces that its first congress will be held in Berlin, Germany, Oct. 11-15, 1926. In the scientific sections question in relation to sexual life will be discussed in regard to society, economic life, hygienics, medicine and law. The principal problems before the congress will be referred in part to committees; other questions will be allowed free discussion. The announcement, which states that the society has been completely reconstructed since the World War, gives a list of prominent members in various countries. including Lépine, Policard and Pézard of France, Recasens, Madrid, Almkvist, Stockholm, Crew, Edinburgh, Freud, Vienna, Leeuwen, Amsterdam, K. Sand, Copenhagen, C. B. Davenport, New York, and Bertrand Russell, London, besides other leaders in sexology from these and other countries. Inquiries concerning the congress should be addressed to Dr. Moll, Berlin W., Kurfürstendamm 45.

Government Services

Permanent Buildings for Army Hospital

Carrying an appropriation of $2,000,000 for continuing the construction of additional permanent buildings at the Walter Reed Hospital, Washington, D. C., the general deficiency bill has passed the House of Representatives. This appropriation authorizes the continuance of construction of additional buildings at the Walter Reed Hospital, to take the place of temporary wooden structures which have, for several years, been in use. A recent survey indicates that the foundations of the present temporary structures are found to be unsafe. Temporary repairs have been made and will continue to be made pending the substitution of the permanent structures authorized by the present appropriations.

Navy Personals

Lieuts. Waldo E. Golden, Edras J. Lanois, Wilbur O. Manning, George L. McClintock and Ashton E. Neely, Medical Corps, U. S. Navy, have been qualified for promotion to the rank of lieutenant commander.——Lieut. Comdr. Fenimore S. Johnson, Naval Hospital, New York, has been ordered to temporary duty in attendance on a course of instruction at the New York Post-Graduate Medical School and Hospital.——The following medical officers have tendered their resignations: Lieuts. Risden J. DeFord, Merrill R. Fox, McClure Scott and William H. Turnley; a later report includes also Lieut. Alan J. Chenery and Lieuts., junior grade, David L. Beers, Frederick S. Foote, and Howard E. Hill.

Appointments and Resignations in Veterans' Bureau

The following changes in personnel in the U. S. Veterans' Bureau are noted in the *Medical Bulletin* for May:

Appointments:

Dr. Louis K. Henschel, specialist in neuropsychiatry, full-time basis, assigned to the regional office in New York.
Dr. Arthur E. Rogers, medical officer (roentgenology), assigned to the hospital at Fort Lyon.
Dr. Hyman D. Shapiro, as assistant medical officer, part-time basis, central office, Washington, D. C.
Dr. Oscar O. Jones, as attending specialist in roentgenology, part-time basis, regional office at Little Rock, Ark.
Dr. Claudius M. Capps, eye, ear, nose and throat specialist, Hospital no. 103, Aspinwall, Pa., Feb. 16, 1926.
Dr. Miles F. Daubenheyer, examiner at regional office, Omaha, Feb. 2, 1926.
Dr. Manuel G. Morales, medical examiner at regional office, San Juan, Porto Rico, Feb. 13, 1926.
Dr. Ira J. Tatum, specialist at regional office, Kansas City, Mo., Feb. 15, 1926.

Resignations:

Dr. L. W. Elwood, as medical examiner at regional office, Omaha, Feb. 15, 1926.
Dr. Carroll Francis at Hospital no. 102, Livermore, Calif., Feb. 25, 1926.
Dr. John L. Hemstead, as medical examiner at regional office, Albany, N. Y., Feb. 28, 1926.
Dr. Frank W. Kern, at regional office, Louisville, Ky., as examiner in general medicine and surgery.
Dr. William B. Lunsford, at Hospital no. 52, Boise, Idaho, Feb. 10, 1926.
Dr. Earl C. MacCordy, at Hospital no. 103, Aspinwall, Pa. (ill health), Jan. 31, 1926.
Dr. Joseph R. Plant, as examiner on claims and rating board, regional office, Sioux Falls, S. Dak., Jan. 15, 1926.

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 15, 1926.

Cause of Mule Spinners' Cancer

The departmental committee appointed by the home secretary to consider the evidence bearing on the occurrence of "Epitheliomatous Ulceration Among Mule Spinners" has presented its report. In the opinion of the committee, the evidence is strongly in favor of the view that this form of cancer is "due to the prolonged action of mineral oils." In other words, this cancer is an industrial hazard. The committee discusses "the substitution of an oil which is innocuous and, at the same time, suitable as a lubricant, due regard being paid to the high rate at which the spindles run." The difficulty, however, is to find the oil, and this is likely to be a prolonged task, since a double problem is involved—that of obtaining innocuous oils and that of blending these innocuous oils so as to get the desired results. In the meantime, the next most obvious remedy is to prevent the oil from coming into contact with the worker. Research is required in this matter, as it is very difficult to prevent "splash" from the bearings. The committee mentions various forms of guard, and speaks with approval of one which consists of a strip of felt or fabric attached to the inside of the wooden door in front of the bolster plate, and projecting vertically about five-eighths inch above the level of the latter plate. "Protective clothing" is not thought to be desirable for a variety of reasons, but constant cleanliness on the part of mule spinners is certainly a safeguard. Further, medical examination at intervals is necessary. The committee recommends, in the first instance, a voluntary system of examination; but if the voluntary system does not result in at least 90 per cent of the workers concerned presenting themselves for each examination, regulations should be made under the factory acts for compulsory examinations. Examinations should take place at least every four months at the factory. They should include every worker in the mule spinning room who is 30 years of age or over.

Cancer Research

At a quarterly meeting of the council of the Royal College of Surgeons of England, Sir John Bland Sutton (president) in the chair, the Walker prize of $500 was awarded to Dr. William Ewart Gye in recognition of his work in advancing the knowledge of the pathology and therapeutics of cancer during the last five years. The award was made in pursuance of the following report from the committee appointed to advise the council in the matter: "The work of Dr. Gye, which has been very materially assisted by the optical research of Mr. J. E. Barnard, F.R.S., promises to throw light on the hitherto unsolved problem of the causation of malignant diseases. Taking as his starting point the pioneer work of Peyton Rous on fowl sarcoma, Dr. Gye produced from this tumor, by different methods, two fluids. Neither of these fluids when inoculated alone produced a tumour, but an inoculation of the mixed fluids in a healthy fowl was followed by the appearance of a sarcoma. The experimenter inferred in his further work that to produce a malignant growth two factors are necessary: first, a living virus which appears to be of extreme minuteness, and, second, a chemical factor peculiar to each species of animal and effective only in that species. Dr. Gye has succeeded in cultivating this virus in vitro. Further, by a series of substitution experiments, he has shown that there can be obtained from human carcinoma and from malignant tumors of the rat and mouse a virus capable of acting with the 'specific factor' of the fowl to cause fowl sarcoma. These experiments, pursued with great patience and acumen over a long period and still in progress, suggest new and hopeful lines of attack on the problem of the cause of malignant disease. Though it cannot yet be said that they have found practical application, they have already given to cancer research such a great stimulus, and such a new direction, as to justify the committee in recommending Dr. Gye for the Walker prize."

Pushing Osteopaths

Notwithstanding the government declaration, all members of parliament have received from the British Osteopathic Association a statement setting out its case and asking "for protection to develop the principles of osteopathy" so that eventually osteopaths "may take their rightful place in the practice of healing." The association asks for a charter for a "British College of Osteopathy."

British Optical Convention

The British Optical Convention has been held at the Imperial College of Science and Technology, South Kensington. It was formally opened by the prime minister. After recalling the predominance of British work in the industry until the latter part of the nineteenth century, Mr. Baldwin outlined the causes that led to our backward position when the Great War came, and caused the government to initiate steps to safeguard optical production and to encourage research. Despite postwar difficulties, British workmanship was now turning out articles that were recognized everywhere for their technical perfection.

The president of the convention, Sir Frank Dyson, astronomer royal, said that the optical industry was almost synonymous with the advance of knowledge and the progress of science. He thought we could say now that our optical manufacturers could make the staple articles—the lenses and the binoculars, and so on—as well as anybody else, and that when they came to those scientific instruments which required a great deal of skill, but which offered very little pecuniary recompense to the optician, they could rely on them to produce what they required. While it could not be asserted that Britain held the preeminent position that it did in the early days of the science, the industry could look back with pride on its achievements and progress during the last twelve years. In 1912, Germany was supplying 60 per cent of the optical glass being used in this country, against 30 per cent made in France and 10 per cent of our own manufacture. When the war made us dependent on our own efforts, the potentiality of the British industry was well shown, and by 1918 the home demand for optical glass for all purposes, which included many new types of lenses and optical instruments requiring glasses of special optical properties, was being met by supplies of which 95 per cent was manufactured in this country. From France came the remaining 5 per cent. At that time we were making 9 tons of optical glass each month. Since the war, owing to the decreased demand, the production had, of course, been much less, but the requirements of British opticians were being met in variety of type and excellent quality.

No convention has been held since 1912, owing to the war, and the exhibition of the convention illustrates developments that have taken place in optical science and manufacture during the last fourteen years. These include new instruments and modifications or new applications of existing instruments. The optical glass industry is now carried on by three firms in this country compared with only one firm before the war, and more than a hundred different varieties of such glass are now produced. The quality of the glass is said to be not merely equal to that obtainable from other sources, but in some respects better, particularly in the matter of transparency. The instrument designed by Mr. J. E. Barnard and Dr. Gye of the National Institute for Medical Research for examining filter-passing virus was shown. The existing type of microscope has been modified for the purpose, and the optical arrangements adopted are also of an entirely new kind, ultraviolet rays being used for the examination of the organisms. The exhibits shown by the Refraction Hospital include a newly designed instrument for measuring the field of vision of the eye, and detecting the presence of any disease impairing it. An instrument has been contrived for training a "lazy" eye back to a state of efficiency. The improvements in lenses include a trifocal lens. This form of lens is intended to benefit the sight of old persons at three different distances. A lens is also shown devised to cut off hurtful rays without the use of tinting. The British Research Association for the Woollen and Worsted Industries has an exhibit which illustrates the work it is doing as a contribution toward the formation of an international standard of fastness for dyes. Progress is being made toward the goal aimed at, though this cannot yet be said to have been reached. A new method of photographic land surveying—the parallacter system—is brought to notice by Mr. J. W. Gordon. It involves the use of a special phototheodolite and of a comparator, and advantages both of cheapness and of facility are claimed for it in comparison with other photographic surveying.

The "Royal Hospitals": The "Spital Sermon"

The annual ceremony in connection with the "Royal Hospitals" is one example of the medieval customs in which this country is so rich. The Easter banquet took place at the Mansion House following the preaching of the "Spital Sermon" at Christ Church, Newgate Street, earlier in the day. A large and distinguished company, which included many representatives of the corps diplomatique, accepted the invitation of the lord mayor and the lady mayoress. Proposing the toast of "Prosperity to the Royal Hospital," the lord mayor said these numbered five. St. Bartholomew's and St. Thomas' were dedicated to the treatment of the sick, Christ's to the education of the young, Bethlem to the alleviation of the insane, and Bridewell also to the education of the young, and, in modern times, to the correction and reclamation of unruly apprentices. St. Bartholomew's dated as far back as 1123. The others were founded, either by King Henry VIII or by his son Edward VI, in the sixteenth century. They were all in existence today, in the highest efficiency and prosperity. The preaching of the Spital Sermon had always been a great feature of Easter in the city. The sermon dated to "time out of mind." It was certainly preached as far back as five centuries ago. It was originally preached in the open air—first at the Spital Cross and afterward in St. Paul's churchyard. There have been occasions when attendance at the Spital Sermon must have been rather an ordeal, for they were told that in 1671 the preacher spoke for three hours, and his sermon, when printed, occupied 230 octavo pages of 27,000 words. The Bishop of Chichester, replying, said that when Queen Elizabeth was present on one occasion at the Spital Sermon she was accompanied by two bears, and after the service attended an exhibition of bear-baiting.

The Intuitive Capacity of Children to Understand Spoken Language

In the *British Journal of Psychology,* Dr. J. W. Tomb, chief medical officer of the Asansol mines' board of health, discusses a subject of great interest. Why is it, he asks, that, whereas British parents in India are usually only just able—or sometimes unable—to acquire a conversational knowledge of an Indian language, their children can often understand two or three Indian vernaculars simultaneously? The capacity of children to understand spoken language, Dr. Tomb concludes, is intuitive and is not a function of intelligence; it is a function of the subconscious mind. Whereas the adult finds the greatest difficulty in learning a new language by the exercise of his reasoning and memorizing faculties, the young child picks it up intuitively. It is commonly assumed that children learn a language as adults do, by the conscious memorizing of parts of speech, moods and tenses, but this cannot be so in the ordinary case of infants learning their mother tongue, the parts of speech, moods and tenses of which cannot be consciously apprehended by them as such, or their use explained to them through the medium of language since they possess none. Moreover, children are universally able to converse freely in their mother tongue without any appreciation of its grammatical construction, which in civilized countries they afterward learn by tedious years of study at school. Infants, therefore, must possess the capacity of intuitively bestowing the correct meanings on the sounds (i. e., words) used in their hearing. In the district in Bengal in which Dr. Tomb resides, he frequently sees English babies of from 9 to 18 months receiving directions and instructions from their mothers in English, from their ayahs in Bengali, and from the house servants in Hindustani, obviously understanding what is being said to them in all these languages long before they themselves are able to speak. Infants appear to comprehend languages in whole sentences, which they endeavor to reproduce in extenso; but, owing to the undeveloped condition of their cerebral cortex and particularly of the speech center, they are unable to do so, merely as a rule producing some simple and easily articulated word belonging to the whole. It is also a common experience of Dr. Tomb to hear English children of 3 or 4 years who have been born in the country conversing freely at different times with their parents in English, with their ayahs in Bengali, with the garden coolies in Santali, and with the house servants in Hindustani, while their parents have learned with much laborious effort just sufficient Hindustani to comprehend what the house servants are saying (provided they do not speak too quickly) and to issue simple orders to them. It is even not unusual to see English parents in India unable to understand what their servants are saying to them in Hindustani, and being driven in consequence to bring along an English child of 4 or 5 years, if available, to act as interpreter. Dr. Tomb describes the case of an English girl, aged 4, who had a Tamil-speaking ayah, her permanent ayah, a Bengali, being ill for two months. Within that period and without any apparent effort, the child was able to understand what the ayah was saying to her in Tamil and to converse with her in that language. Moreover, the child continued to speak occasionally in Tamil to the other servants for some time after her Tamil-speaking ayah had gone away, apparently not recognizing that she was speaking to them in a language which they did not understand. Such a case as this can be satisfactorily explained only on the hypothesis that the child "intuitively" and subconsciously placed the correct meanings on the various sounds (words) in Tamil which the ayah used to her in conversation, and was unaware of any difference between the various languages (English, Bengali, Santali, Hindustani, Tamil) that she was able to speak.

Rockefeller Foundation Gift

The Medical School of St. Thomas' Hospital has received a gift of $75,000 from the Rockefeller Foundation toward the building of new laboratories for the education of the students. The laboratories will be situated within the hospital and will be easily accessible from the wards. The medical school has for some time past been considering the question of providing permanent quarters for the students' laboratory, up to now situated in old army huts, and has to this end put by $75,000, but has been unable to begin the building until a further sum of $75,000 could be provided. The generous gift of the Rockefeller Foundation will enable the erection of the laboratories to be begun at once on a site provided by the hospital.

Deplorable Conditions in the Roumanian Universities

The idea of the numerus clausus, or percentage quota, which caused distress among university students in Hungary, has spread to Roumania. But, whereas in Hungary the quota allows the admission of a few Jewish students, in Roumania Jewish students have been barred and the universities closed for more than a year so that students of all creeds have lost two semesters. Mr. I. Yevin, who came to Roumania to study the situation in the universities, writes in a recent number of a leading weekly paper that the first thing that strikes one about the university building in Bucharest or Jassy is that it is surrounded by soldiers. Each Jewish student was surrounded on entrance and was offered the alternative of being thrashed or of signing a document that he voluntarily withdrew from the university and would not attend any more lectures. Many, faced with this alternative, have signed the declaration.

The professors and lecturers are intimidated. The university officials are at the mercy of the antisemitic student bodies, says Yevin.

When the university senate decided to expel the ringleaders of the disturbances, the minister of education vetoed the decision. When the council of professors intervened on behalf of the Jewish professor Dr. Reiner, who was insulted by his students and compelled to keep away from the university, the minister of education asked for a statement from the students; they supplied a memorandum and the matter was closed.

The new examination system introduced by the department of education has proved an effective bar to the majority of Jewish students.

Distribution of Prizes in the Medical Society

The Budapest Royal Medical Society held its general meeting some days ago. In his opening address the president, Dr. Koloman Buday, announced that the society must depart from its custom of distributing monetary prizes among those who had recently contributed valuable scientific works to Hungarian medical literature. This time the society is in a position to give only diplomas of merit because of depreciation of the currency. The Balassa and Meszarosf funds before the war amounted to $6,000. The interest on this amount was then $500. Now the interest is worth only a cent and a half. "We entertain the hope," concluded the president, "that the winners of this year's competition will not regard the diplomas of merit handed to them as mere sheets of paper but that they will value this distinction, which joins their names to those of their glorious predecessors who earned the admiration of the Hungarian medical profession, and the entire world. Diplomas of merit have been awarded to Professor Michael Lenhossék for his textbook, "The Anatomy of Man"; Tivadar Bársony and Béla Hortobágyi, for their work on the duodenal pyloric reflex; Andor Bosányi, for researches on the pathogenesis of rachitis; Lászlo Csáky and Béla Molnar, for work on the thesis that hyperacidity is a disturbance of salt metabolism; Francis Kiss, for his research on the histology of the blood vessels; Joseph Duzár, for investigation of the hormone treatment of chorea minor; Louis Bakay, for his work on the replacement of the esophagus; George Gortvay, for his views on the social hygienic protection of workmen; Hugo Preisz, for investigations on bacteriophagy. The board of the society has elected as corresponding members Profs. John Howland, Baltimore; Ernest Graham Little, London; Leonard Findlay, Glasgow; F. Biedel, Prague; Jose Brito y Foresti, Montevideo; I. van Holve, Leyden; C. Neuberg, Berlin

The Congress of Internal Medicine

This letter continues my report on the annual session of the Deutsche Gesellschaft für innere Medizin held in Wiesbaden, April 12-15 (THE JOURNAL, May 29, p. 1710).

THE BLOOD AS CLINICAL REFLECTOR OF SOMATIC PROCESSES

Prof. V. Schilling of Berlin, in his paper on "The Blood as the Clinical Reflector of Somatic Processes," made the following statements: The morphologic study of blood processes has been practically completed. However, the most recent conception, the reticulo-endothelial monocyte system, needs to be inquired into further. The division of the blood processes and of blood diseases as clinically separable processes within the scope of these systems has been found tenable: systemic reactions and systemic affections are characteristic of the changes in blood pathology. Differentiation of the systems must, however, be studied not only from the morphologic but also from the functional standpoint. The characteristic shapes of the cells are an indication of their peculiar capacities and functions. Even minute departures from the normal in blood make possible deductions as to the histologic changes in the hematopoietic organs. For that purpose a large number of critical observations on histologic material are already available whereby the connections between the peripheral blood picture and the changes in the extensive hematopoietic regions of the body have been adequately explained. Not only researches on the minute details of internal cell structure, so-called "intracellular pathology," but also the study of humoral colloid changes point out new ways for the elucidation of the functional significance of those changes. The processes which control the leukocyte apparatus may be regarded as parallels of the "inflammation processes." They comprise nervous and vascular, colloido-chemical and chemical, hormonal and endocrine changes or disorders. The pathologic process is an accentuation of normal controls and a modification that meets the new demands of the pathologic environment. The clinical scope of these blood processes comprises, medically, latent disturbances that have not yet manifested themselves as "disease"; regular associated conditions of very many and manifold disease processes—especially those of an infectious and toxic nature, and on down to the cardinal aspects of the "blood diseases." The best form of research has been the study of the microscopic blood preparation, extended in special cases, when the need was felt, by the actual cell counts, a few special color tests, certain auxiliary methods, such as the sedimentation test, the determination of resistance, colorimetry, and physical and chemical supplementary tests. In the large majority of cases, however, the skilled investigator can recognize from the single, carefully scrutinized blood preparation not only the cytologic modifications of the peripheral blood picture but also the signs of the inner histologic changes and the modified functions of the organism, and thus gain an insight into the momentary status of the vital processes in the deeper tissues. Repeated observation will reveal to him the course of reactions, which take place according to definite "laws" though they may not always be understood. Blood examination is coming to be a continuous study of cellular pathology on the living organism. The skilled clinician should get from these observations, which he must associate with the general condition of the patient, an idea concerning the nature and the course of the disease process. That this is possible, in the main, through the application of simple principles, although much is yet to be learned, is shown by the practical results of internal medicine, surgery, gynecology, pediatrics and tropical pathology, and many investigations, conducted with great care, in such specialties as tuberculosis, the hygiene of sport activities, inoculation malaria and recurrent fever, and the control of various forms of treatment.

During the discussion, Stettner of Erlangen observed in a child shifting of the blood picture to the right and relative lymphocytosis, which permit a differentiation according to age. Arneth of Münster regards shifting of the blood picture to the right as equally important with shifting to the left. He demands the observation of the nuclei and protoplasm and a uniform acceptance of his system by investigators. The reaction phases of Schilling he regards as reaction types. Curschmann of Rostock reported on the resistance of hemoglobin to sodium hydroxide. In pernicious anemia, an increased resistance is noted.

Death Following Rapid Absorption of Fluid of Edema

A case of sudden death from rapid absorption of the fluid of edema occurred recently at the medical clinic of the University of Geneva (service of Prof. Roch). A man, aged 68, a cardiorenal subject, had been energetically treated with diuretics for some time, but without avail. Then suddenly, without any apparent cause, a formidable diuresis ensued following a dose of theophylline sodio-acetate, which up to that time had been ineffective. Sudden death followed. The pathogenesis of the process is not clear. Dr. Illitch, who studied this case, after summarizing the various theories, takes up the theory of anaphylactic shock. According to this theory the disturbances are due not merely to a sudden excessive loss of fluid, but above all to a colloidoclastic shock resulting from the passage of the serum in the tissues into the circulation. The albumins contained in the fluid of edema have, in respect of the albumins of the blood serum, the same action as heterogenous albumins foreign to the blood. This theory explains why the accidents never ensue when the serous fluid is eliminated, even in large amounts, by puncture or blistering. It also explains why disturbances develop before the onset of diuresis from mere mobilization of the fluids of the edema. The analogy between the clinical accidents of absorption and those of anaphylactic disturbances is remarkable, to such a degree that following mobilization of the fluids of edema the fundamental signs of anaphylactic shock are encountered, viz.: a fall of the blood pressure, transitory massive albuminuria and leukopenia.

Blood Calcium

Calcium in the blood has recently been the object of research work by Dr. E. Wyss at the surgical clinic of the University of Geneva. Being in perfect health, Wyss experimented on himself. For two days he took 6 Gm. of calcium phosphate, and then 8 Gm. daily for five days, a total of 52 Gm. in one week. On the eighth day the blood contained calcium as follows:

8 a. m. (fasting)	0.146 per cent
10:15 a. m.	0.142 per cent
2:30 p. m. (after lunch)	0.140 per cent
6:15 p. m.	0.146 per cent

Wyss found that the calcium content of the blood when the salt was not ingested varied between 0.168 and 0.106 per cent. When the salt was ingested, the calcium content of the blood averaged 0.142 per cent.

Wyss next experimented with calcium in fractures. In five cases he was able to increase the calcium content of the blood, although in one instance, in spite of continued ingestion, the blood content dropped to normal. He concludes also that sex influences the calcium content of the blood; in men it varies from 0.12 to 0.165 per cent; in women, from 0.11 to 0.126 per cent. Age has no influence. Puberty in the female decreases the content. The content is physiologically variable from one hour to another, and is low during digestion. Trauma does not decrease the calcium content during the process of cicatrization. Ordinary fractures or pseudarthroses have no effect on the calcium content. Calcium treatment stabilizes the content in healthy subjects and may increase it for a time, but does not prevent reestablishment of the normal even when treatment with the salt is continued.

Dr. Hugo Oltramare of Geneva showed that sudden change of diet involving a marked decrease of the calcium intake reduces the calcium content of the blood, but this is only temporary. Treatment with lime-water, when the calcium blood content is normal, produces a temporary increase at the beginning of treatment. The calcium content of food in a normal diet seems to be always sufficient. Therefore a low blood calcium content must be explained by either disturbed assimilation or a disturbed metabolism. The ingestion of fresh thyroid gland appears to throw a large quantity of lime into the circulation.

Sex Education

In an address on "Sexual Education During the Years of School Life," Dr. J. Golay of the Faculty of Geneva said that sexual education had become a necessity. If numerous attempts so far undertaken had been fruitless, it is because the necessity of this teaching has not penetrated the public mind, and also because too much moralizing has been done. Golay suggests that teaching should dwell on birth, sex and venereal disease. A child should be frankly told that his mother carried him within herself and this knowledge will develop filial respect and will show reproduction as a sacred function. The child should be taught the reproduction in plants and then in animals, thus progressively ascending the series. Thus the child will grasp the great laws of fecundation and will know that the majority of living organisms can be reproduced only by a conjugation of the male with the female element. Young people should know about puberty. Boys should be taught to avoid those excesses which injure both morals and the body. Girls are to be warned against seductions, and they should be given a clear understanding of their future duties by developing in them their maternal instinct. The adolescent should know that if he gives way to sexual perversions and onanism he will have the greatest difficulty in giving up the habit. If, in spite of the teaching, parents detect something abnormal in the child, they must speak seriously without frightening the child.

Many physicians and educators recommend diverting the sexual instinct by occupations requiring an expenditure of physical strength, such as sports and life in the open. Dr. Golay thinks it is an error to suppose that physical exercise kills the instinct. Intense intellectual work is, perhaps, the best substitute, but since the laws of hygiene prohibit this in young people, the child must be taught to use his will power. Between 16 and 18 years of age is the time to instruct young people in the pathology of venereal disease. The public should be made to understand that these diseases are not shameful per se. Therefore children will understand that they can confide in their parents, with the result that proper treatment will be undertaken while the disease is still curable.

In public lectures on venereal diseases it is usual to dwell lengthily on their disastrous consequences, probably for the purpose of fright; but morality obtained by fright is no longer morality. For that matter, the phobia of the sexual act does not lead, as might be supposed, to chastity but to perversions. The object of sexual education is to develop morality by a healthy and normal comprehension of natural phenomena and make our sons conscious of their duties and responsibilities.

Marriages

John Bernard Thompson to Mrs. Florence Foley, both of Wittenberg, Wis., March 22.

Andrew Christiansen, St. Paul, to Miss Olive Hamburg of Minneapolis, in April.

Daniel N. Williams to Miss Frances Blair, both of Chattanooga, Tenn., recently.

Deaths

Jesse Leland Boogher ⊕ St. Louis; Washington University Medical School, St. Louis, 1892; formerly professor of genito-urinary surgery, Barnes Medical College; member of the American Urological Association; secretary of the Section on Diseases of Children, of the American Medical Association, 1898-1899; aged 58; died, April 17, at the Missouri Baptist Sanitarium, following an appendectomy.

Henry Beates, Jr. ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1879; for many years president of the state board of medical examiners and formerly president of the Federation of State Medical Examining and Licensing Boards; member of the Philadelphia Pathological Society; aged 68; died, May 25.

Gordon Bryan Crowell, Lincolnton, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1922; member of the Medical Society of the State of North Carolina; served during the World War; on the staff of the Lincolnton Hospital, where he died, May 9, of influenza and peritonitis, aged 30.

Thomas W. Rogers, New London, Conn.; Medical Department of Columbia College, New York, 1890; member of the Connecticut State Medical Society; formerly on the staff of St. Luke's Hospital, New York; aged 72; died, May 19, of cerebral hemorrhage and arteriosclerosis.

Carlos A. Fish, Frankfort, Ky.; Southwestern Homeopathic Medical College and Hospital, Louisville, 1901; member of the Kentucky State Medical Association; aged 51; died, in May, at a sanatorium in Battle Creek, Mich., of heart disease following influenza.

Albert Leonard Bennett, Denver; University of Colorado School of Medicine, Denver, 1897; for many years on the staff of the Mercy Hospital; formerly a medical missionary in China and Africa; aged 62; died, May 5, at Chicago, of pneumonia.

Frank M. Virtue ⊕ Sulphur Springs, Ohio; Western Reserve University School of Medicine, Cleveland, 1887; president of the Crawford County Medical Society; member of the school board; aged 62; died, in May, of heart disease.

Peter MacNaughton, Brockville, Ont.; Trinity Medical College, Toronto, 1888; member of the American Psychiatric Association; medical superintendent of the Ontario Hospital for the Insane; aged 67; died, March 7, of pneumonia.

Ten Eyck Olmstead Burleson, Bath, N. Y.; University of Buffalo Department of Medicine, 1880; for ten years connected with the New York Soldiers' and Sailors' Home; aged 72; died, May 13, of cerebral hemorrhage.

Franklin Campbell Jillson ⊕ Boston; Medical School of Harvard University, Boston, 1886; served during the World War; aged 62; on the staff of the Faulkner Hospital, where he died, May 7, following a long illness.

Hiram E. Connor, Brookhaven, Miss.; Harvey Medical College, Chicago, 1900; formerly lecturer on genito-urinary diseases, at Flint Medical College of New Orleans University; aged 48; died, February 23, of pneumonia.

James L. Fuller, Warrensburg, N. Y.; Dartmouth Medical School, Hanover, N. H., 1882; formerly member of the state legislature; president of the North Creek National Bank, aged 70; died, May 15, of thrombosis.

Hugh D. Hamilton ⊕ Kansas City, Mo.; Missouri Medical College, St. Louis, 1898; served during the World War; on the staff of St. Joseph's Hospital, where he died, May 14; aged 53, of carcinoma of the kidney.

Edward L. Welbourn, Union City, Ind.; Eclectic Medical College of Pennsylvania, Philadelphia, 1866; for many years secretary of the board of health; aged 83; died, May 6, at Los Angeles, following a long illness.

Ralph Steiner ⊕ Austin, Texas.; University of Maryland School of Medicine, Baltimore, 1883; formerly state health officer, and president of the state board of health; aged 67; died, May 2, of pernicious anemia.

Caleb J. McNulty, Washington, Pa.; Western Reserve University School of Medicine, Cleveland, 1869; Civil War veteran; formerly a druggist; aged 85; died, April 29, of pneumonia following influenza.

Russell Franklin Benson, Jr. ⊕ Troy, N. Y.; Medical Department of Columbia College, New York, 1876; New York Homeopathic Medical College, New York, 1877; aged 74; died, March 28, of pneumonia.

William C. Looney, Normandy, Tenn.; University of the South Medical Department, Sewanee, 1900; mayor of Normandy; aged 69; died, April 7, at a hospital in Shelbyville, following a long illness.

Ripley C. Hoffman ⊕ Deming, N. M.; Jefferson Medical College of Philadelphia, 1883; past president of the Luna County Medical Society; formerly mayor; aged 66; died, May 7, of heart disease.

Harry George Macdonald ⊕ Hackensack, N. J.; College of Physicians and Surgeons, Baltimore, 1903; served during the World War; on the staff of the Hackensack Hospital; aged 46; died, May 19.

William Edward Sharp, Pascagoula, Miss.; Mississippi Medical College, Meriden, 1909; member of the Mississippi State Medical Association; aged 52; died, March 16, of general paralysis.

Grandison C. Edwards, Hookerton, N. C.; Bellevue Hospital Medical College, New York, 1883; member of the Medical Society of the State of North Carolina; aged 68; died, May 8.

Austin John Blanchard, Jamaica, N. Y.; Long Island College Hospital, Brooklyn, 1892; formerly on the staff of St. Mary's Hospital, New York; aged 69; died, May 9, of cerebral hemorrhage.

John Howard Vorhes ⊕ Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1912; served during the World War; aged 38; died, in April, of tuberculous meningitis.

George M. Combest, Lamar, Okla.; College of Physicians and Surgeons, Dallas, Texas, 1905; served during the World War; aged 59; died, February 10, of carcinoma of the stomach.

William David Morrison Bell, Ottawa, Ont., Canada; University of Bishop College Faculty of Medicine, Montreal, Que., 1882; aged 67; died, March 14, of cerebral hemorrhage.

Maro Johnson Love, Bloomingville, Ohio; Long Island College Hospital, Brooklyn, 1871; formerly member of the state legislature; aged 78; died, April 12, of valvular heart disease.

Frank H. Kimball, Rockford, Ill.; Chicago Medical College, 1880; aged 70; formerly on the staff of the Rockford City Hospital; where he died, May 8, following a long illness.

Henry Gwynn Branham, Baltimore; Maryland Medical College, Baltimore, 1905; aged 42; was drowned, in May, when he fell into a shallow spring at Okahumpka, Fla.

Julius Rudisch, New York; University of Heidelberg, Germany, 1874; for many years on the staff of Mount Sinai Hospital; aged 78; died recently, at Doylestown, Pa.

W. J. Barker, Trenton, Tenn.; Memphis Hospital Medical College, 1901; member of the Tennessee State Medical Association; aged 50; died recently, of pneumonia.

Isaac A. Bigger ⊕ Rock Hill, S. C.; Medical College of the State of South Carolina, Charleston, 1889; aged 58; died, May 6, at Cedar Crest, following a long illness.

Edward Jerome Ziegler, Oxford, Wis.; Milwaukee Medical College, 1911; member of the State Medical Society of Wisconsin; aged 42; died, April 23, of appendicitis.

James H. J. Flynn ⊕ New Haven, Conn.; Yale University School of Medicine, New Haven, 1895; aged 52; died, April 26, of angina pectoris and coronary embolism.

John Baker Morris, Lewiston, Idaho; St. Louis Medical College, 1874; for ten years mayor of Lewiston; aged 75; died, March 26, of carcinoma of the liver.

George B. Hennigh, Perkasie, Pa.; Baltimore Medical College, 1891; formerly postmaster of Sykesville; aged 63; died, April 6, of carcinoma of the liver.

Mary Augusta Brown Girard, San Francisco; Northwestern University Woman's Medical School, Chicago, 1883; aged 90; died, May 15, of chronic myocarditis.

Mont H. Cassidy, Milan, Mich.; Michigan College of Medicine and Surgery, 1892; aged 70; died, April 30, at Monclova, Ohio, of cerebral hemorrhage.

James J. Coppedge, Lone Oak, Texas; University of Louisville School of Medicine, 1887; formerly a minister; aged 78; died, April 29, of pancreatitis.

Abraham S. Gish, Abilene, Kan.; Eclectic Medical College of Pennsylvania, Philadelphia, 1869; aged 82; died, April 25, of cerebral hemorrhage.

Albin Wilshire Lipscomb, New Market, Ala.; Vanderbilt University Medical Department, Nashville, 1896; died, April 28, of pneumonia.

Allen Corson Cowperthwaite, Los Angeles; Hahnemann Medical College of Philadelphia, 1869; aged 77; died, March 1, of chronic myocarditis.

Frederick Lucian Brigham, Wolcott, Vt.; Dartmouth Medical School, Hanover, N. H., 1887; aged 64; died recently, of cerebral embolism.

Joseph Trimble Ricker, Loveland, Ohio; Eclectic Medical College of the City of New York, 1871; aged 77; died, May 4, at Epworth Heights.

William C. Baker ⊕ Hummelstown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1874; aged 76; died in April.

Charles Campbell Moffett, Elyria, Ohio; Western Reserve University School of Medicine, Cleveland, 1890; aged 58; died, March 17.

William Henry Bourns, Frankville, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1892; aged 64; died, March 11.

Charles H. Siegrist ⊕ Uhrichsville, Ohio; Ohio Medical University, Columbus, 1896; formerly a druggist; aged 58; died, April 30.

Frank C. Combes ⊕ New York; Bellevue Hospital Medical College, New York, 1883; aged 63; died, April 18, of cerebral hemorrhage.

William I. Swangem, Terrell, Texas: University of Louisville (Ky.) School of Medicine, 1890; aged 69; died, March 4, of paralysis.

Charles Sumner Fischer, New York; Long Island College Hospital, Brooklyn, 1887; aged 60; died, May 13, of pneumonia.

William H. Hinkle, Degraff, Ohio; Medical College of Ohio, Cincinnati, 1886; aged 77; died, April 9, of general paralysis.

Edward Felix Hixon, Vancouver, Wash.; Victoria University Medical Department, Toronto, 1884; aged 70; died, April 26.

Hugh Kennedy Hyndman, Exeter, Ont., Canada; Western University Medical School, London, 1886; aged 62; died, March 6.

Laurent S. Mitchell, New York; New York Homeopathic Medical College and Hospital, 1895; died, May 10, of heart disease.

Charles Aronson, Los Angeles; Tufts College Medical School, Boston, 1916; aged 30; died, April 6, of brain tumor.

Samuel E. Hassell, Lancaster, Wis.; Hahnemann Medical College and Hospital, Chicago, 1872; aged 78; died, April 25.

Charles William Bonar, West Liberty, W. Va.; (licensed, West Virginia, 1881); aged 77; died, March 3, of senility.

John Andrew Taulbee, Mounds, Okla.; Kentucky School of Medicine, Louisville, 1889; aged 77; died in March.

George Sherman Haswell, Watervliet, N. Y.; Albany Medical College, 1892; aged 57; died, April 28.

John L. Goff, Litchfield, Neb. (licensed, Nebraska, 1891); aged 80; died, March 16, of lobar pneumonia.

Frank Scott, Rogers, Ohio; Cleveland Medical College, 1877; aged 81; died, May 18, of pneumonia.

Edward O. Smith ⊕ Winfield, Kan.; Keokuk (Iowa) Medical College, 1895; aged 57; died in April.

George W. Callis, Dyer, Tenn.; Memphis Hospital Medical College, 1885; aged 78; died, February 23.

Milton W. Sparks, Terre Haute, Ind.; Louisville National Medical College, 1896; died, March 31.

CORRECTION

Frank M. Baldwin.—The late Dr. Frank M. Baldwin, whose obituary was published in THE JOURNAL, May 22, resided at Blanchester, Ohio, instead of Columbus.

Correspondence

POSTMORTEM RECORDS OF HOSPITALS

To the Editor:—We have read with a great deal of interest the article by Christian (THE JOURNAL, May 15) entitled "Selecting a Hospital for Internship."

At the outset, we wish to subscribe heartily to the statements as to the importance of necropsies and their value as a teaching medium, both for the staff and for the interns. The Newark Beth Israel Hospital, with an active 125 bed general service, of which about 60 per cent are ward beds, is supported by the Jewish Community but is nonsectarian in its policies, treating about 45 per cent of non-Jewish patients. During the year 1925 there were 182 deaths in the hospital, in thirty-eight of which, or 20.9 per cent of all deaths (both private and ward), necropsies were held.

Realizing the importance of necropsies and desirous of getting a greater percentage of our deaths to the postmortem room, we undertook a vigorous campaign among the physicians sending patients to the hospital, and among the lay public of our community, in an endeavor to do away with the prevalent, traditional prejudice against the performance of necropsies. In addition, Jan. 1, 1926, we established a routine to make sure that the relatives of all persons dying in the hospital would be interviewed for the purpose of obtaining permission for a necropsy. A form must be filled out in every death, either granting or refusing this. In difficult cases, the pathologist or the attending physician, or both, is called in in an effort to convince the relatives of the importance of this final examination.

Since adopting this plan, we have had to date seventy-three deaths, of which thirty-seven have come to necropsy. Of these deaths thirty-four are Jewish with seventeen necropsies, and thirty-nine are non-Jewish with twenty necropsies. These figures show that whatever religious scruples might exist against necropsies, they are not very strong and that careful and sympathetic arguments can overcome them.

PAUL KELLER, M.D., Superintendent,
MAX DANZIS, M.D., Chief of Staff,
ASHER YAGUDA, M.D., Pathologist,
Beth Israel Hospital,
Newark, N. J.

THE OMENTUM

To the Editor:—I note with interest your current comment on the omentum (THE JOURNAL, April 24). I wish to suggest that it never has been proved that peristalsis or change in position of the body will cause the omentum to move. In fact, it has been proved that it does not. When an area becomes inflamed, the omentum becomes hyperemic followed by exudation and leukocytic extravasation. Then and not until then does the omentum move. When the omentum begins to move, peristalsis has already ceased because of the inflammatory reaction within the gut walls. (Compare "Causes of the Migration of the Omentum," THE JOURNAL, April 26, 1913, p. 1292). ARTHUR E. HERTZLER, M.D., Halstead, Kan.

CONTROL OF NARCOTICS

To the Editor:—Following suggestions in THE JOURNAL of recent date, we have sent a letter to President Coolidge, the Committee on Ways and Means, the Committee on Finance of the U. S. Senate, the Secretary of the Treasury, Hon. William Williamson, Hon. W. H. McMaster, and Hon. Peter Norbeck protesting against S. 4085, which was introduced in Congress, April 24, at the instance of the Treasury Department. We have had a reply from our congressman, William

Williamson, and from one of our senators, Peter Norbeck, in which they say that S. 4085 has not been called to their attention by protest before ours. They both assure us that they will look into the proposed questionable legislation. I am wondering whether you should not put forth further effort to stir physicians up in this matter.

C. F. Morsman, M.D., Hot Springs, S. D.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SHELL SHOCK

To the Editor:—Kindly give me the prevailing opinion as to the definition of "shell shock." Is shell shock ever caused in a perfectly normal person, one who has seen something of life, one who has been tried, one with a perfectly good family history? Is it, or is it not, a sign of "weak brother"—an unstable character? Do we, or do we not, see a similar condition in soldiers who were not under fire?

West Virginia Inquirer.

Answer.—Histologic study of the nervous systems of men who had died after being subjected to the explosion of a shell without signs of external bodily injury revealed certain changes that were attributed to concussion. From this observation it was concluded that many of the heterogeneous symptoms of nervous disorder observed in nonfatal cases might be due to changes of the same character, and they were consequently called shell shock. The occurrence of exactly similar symptom complexes, however, without exposure to shell explosions even among men in camp in America who had never seen a shell fired, the fact that "shell shock" was not observed among men captured as prisoners even though many of them had been blown up by shells and more or less seriously injured, and the results that were obtained from clinical study and psychotherapy in men classed as "shell shock" demonstrated conclusively that this term was a misnomer and the title was officially discontinued soon after the United States entered the war by the Surgeon General of the army. Instead, these cases were classified as neuroses or psychoneuroses entirely comparable to the similar conditions arising in civilian life, and the essentially mental nature of the disorders was recognized. Probably the best description of the nature of these disabilities is that which characterizes them as a means of escape from an intolerable situation.

The conception of "a perfectly normal person" is quite untenable. Normality of a person, that is to say of the man as a whole, can mean nothing else than successful adaptation to the surroundings in which he is placed. Man must struggle for the satisfaction of his instinctive longings and needs with the circumstances of whatever may happen to be his social environment from time to time. No one method of securing satisfaction can be said to be "normal," though some methods will be more satisfactory than others. Probably the best answer to the question can be given by pointing out that men broke down with psychoneuroses (or "shell shock") at every stage of the army career from enrolment to rehabilitation in civil life. In spite of the successive eliminations of persons unable to make the grade of the "intolerable situations" encountered during the successive steps, large numbers of psychoneuroses developed even among men in the firing line, men who, on the whole, may be regarded as a group of the healthiest and "most normal" of the young manhood of the nation. It is true that studies of family histories revealed a greater proportion of "nervous taint" among those who broke down than among those who did not, but it must also be remembered that there are few families in which such taints cannot be found if sought. It also seems justifiable to conclude that persons who are least well equipped by inheritance and training for facing difficulties will break down under the smallest stress, but what weight should be given to breeding and how much to training is not known; the fact that more than 90 per cent of the men at the front who developed psychoneuroses were able to return to duty within three months under treatment by measures that were essentially training or educational in nature must be considered highly significant.

There is no essential difference between the psychoneuroses developing in the army and those that arise in civil life. The circumstances surrounding the man at the time are different and the nature of the "intolerable situations" is different, so that the actual symptomatology is likely to vary. It may be pointed out here that the psychoneuroses among ex-service men today have arisen not on the basis of war difficulties but rather on those inherent to readjustment to civilian life, even though, as would be expected, the army experience is used in the construction of the particular symptoms presented.

Recognition of the nature of these disorders came largely from experience during the World War. It is impossible, therefore, to compare statistically the frequency in that with those in the Civil War. But that similar psychoneuroses were common in the latter is well known and, in illustration, attention may be called to the reports of Da Costa on functional heart troubles in Civil War soldiers.

INFANTILE TETANY

To the Editor:—I should like to know the symptoms of infantile tetany and treatment of a case in a boy, aged 18 months. Please omit name.

M.D., Pennsylvania.

Answer.—Tetany is frequently associated with rickets. The condition occurs most frequently toward the close of winter and in the early spring months. Carpopedal spasm is one of the early symptoms. This is a tonic spasm that involves the hands or feet. The hands assume the so-called obstetric position, with the fingers and thumb approximated and with contracture at the wrist. The arms are often held against the chest. The lower extremities are not always involved, but if they are there is flexion at the knee joint and the feet are held in the position of equinovarus. Occasionally edema of the dorsal surfaces of the hands and feet occurs.

Generalized convulsions are of common occurrence and may be observed in the latent type of the disease as well as in the manifest. The spasm generally starts in the muscles of the eye and face and then rapidly extends to the extremities. Relaxation occurs soon after the convulsion, and consciousness returns almost immediately. In this way the convulsions of tetany differ from epileptic seizures.

Laryngospasm is a characteristic symptom and may occur early in the affection. It consists of a peculiar crowing inspiratory sound. Laryngospasm may be followed by convulsions.

In addition to these symptoms there are several characteristic signs. These may be observed in the latent type of the disease. The Trousseau phenomenon is elicited when the arm above the elbow is constricted. When this occurs, the child's hand will assume the contracted tetany position. The Chvostek sign is elicited by tapping the cheek over the superficial course of the facial nerve. If tetany is present, lightning-like contractions occur over all parts of the face controlled by the facial nerve. The Erb phenomenon represents a hyperexcitability of peripheral nerves, as determined by the use of the galvanic current.

It has been definitely shown that the calcium content of the blood is materially reduced in cases of tetany. In contradistinction to this, the phosphorus is almost always reduced in rickets.

Children suffering from active tetany should be given 1 Gm. of calcium chloride by mouth every four hours for the first two days. If the symptoms subside, 0.65 Gm. of the drug should be given four times a day for three or four days, and then from 0.3 to 0.65 Gm. three times a day for two weeks. If convulsions occur, chloral hydrate and calcium bromide should be used in appropriate doses. Ultraviolet irradiation seems to cause an increase of the serum calcium and is undoubtedly of value in these cases. Four cubic centimeters of cod liver oil two or three times daily should also be given, particularly in view of the fact that rickets and tetany are usually coexistent.

ENDOTHELIAL SYSTEM—DOROTHY REED CELL

To the Editor:—Kindly define the following terms: (1) reticulo-endothelial system of the skin; (2) the Dorothy Reed cell in Hodgkin's disease. Kindly omit name.

M.D., Connecticut.

Answer.—1. The reticulo-endothelial system, as described by Aschoff and Landau (1913), includes ordinary endothelial cells, fibrocytes, reticular cells of the spleen and lymphoid tissues, the reticulo-endothelium of the spleen, lymph and marrow sinuses, of the lung, suprarenal and hypophysial capillaries, the Kupffer cells of the liver, the histiocytes or clasmatocytes and the splenocytes and blood monocytes, named in the order of increasing phagocytic properties by which they are generally recognized. In the corium and subcutaneous connective tissue there would be the endothelium of the capillaries and lymph spaces, reticular cells, fibroblasts and the highly phagocytic clasmatocytes, which were described by Ranvier as long, branching cells with oval nuclei and finely granular cytoplasm and are evidently the same as some at least of the macrophages of Metchnikoff. These different cells, all of mesodermal origin, are not highly differentiated, and under proper stimulus any one seems to be able to produce any of the other forms. The extent of this system, the number of cells that may become actively phagocytic in the whole cutaneous organ, is incalculable. Pursuant on their phagocytic function there is evidence also that these cells produce such substances as bilirubin from hemoglobin and antibodies. Textbooks on diseases of the skin have practically no reference to this system, so the more general studies must be consulted.

2. In recent writing the term "Dorothy Reed cell" appears only occasionally. Therefore, the general medical reader will find difficulty in identifying the cell among the several unusual types characteristic of the disease. MacCallum, in "A Text Book of Pathology," third edition, page 859, although he does not use the name Dorothy Reed cell, describes it as follows: "Among these cells there are found much larger ones which constitute the most characteristic feature of the lesion. These are really quite large cells, and while they vary greatly, are many times the size of the lymphocytes. Their protoplasm is clear except for scattered, irregular stainable shreds, and their outline is rather ragged. They contain one or two or several large nuclei, which are rounded or indented or lobed and usually lie close together. These nuclei are very sharply outlined with a deeply staining chromatin membrane, within which the nuclear substance is relatively sparsely granular. In each nucleus there is a large nucleolus, sometimes two, and these nucleoli stand out very clearly with a deep stain." Dr. Reed's description of the lesions of Hodgkin's disease appeared in *Johns Hopkins Hospital Reports* (**10**:133, 1902), under the title "The Pathological Changes in Hodgkin's Disease."

VISIBILITY OF SIGNS

To the Editor:—I should like information regarding the visibility of different colors for street signs. Which would be the most visible:

White letters on black background
White letters on blue background
Black letters on white background
Black letters on yellow background?

T. W. ASHLEY, M.D., Kenosha, Wis.

ANSWER.—The visibility of different colors for street signs would depend to a great extent on the illumination under which the street signs were to be seen. In general, black letters on a white background would offer sharper contrast than any other combination, particularly in diffuse daylight. But this offers the disadvantage that in the average city where the street signs would be used, there is so much smoke in the atmosphere that the white background soon becomes a dirty gray and the contrast is lost. This holds true to a lesser extent of other backgrounds. White letters on a blue background form a favored combination in many cities, and seem to retain their contrast despite atmospheric dirt fairly well.

EFFECT OF SMOKING ON BREAST MILK

To the Editor:—I have a patient with a 4 weeks old baby. The mother is an inveterate cigaret smoker. The baby has diarrhea from no apparent cause. I have stopped the mother's smoking. I wondered whether nicotine could be excreted through the breast milk. What effect would this have on the baby's bowels?

JOSEPH HALTON, M.D., Sarasota, Fla.

ANSWER.—In nursing mothers who smoke excessively, nicotine may be found in the breast milk. Since diarrhea is one of the symptoms of nicotine poisoning in adults, it might conceivably occur in infants also. Lesage asserts that wetnurses who smoke or chew tobacco can poison the babies they nurse and the symptoms produced are digestive disturbances, restlessness, dyspnea, bradycardia, syncope, collapse and death. However, such a result must be a great rarity; for in the experience of one of the leading pediatricians in the country, no harm has ever been observed in babies nursed by mothers who smoke inordinately. Heavy smokers, as a rule, cannot nurse their babies very long.

COMING EXAMINATIONS

ALABAMA: Montgomery, July 13-16. Sec., Dr. S. W. Welch, Montgomery.

ARIZONA: Phoenix, July 6. Sec., Dr. W. O. Sweek, 404 Heard Bldg., Phoenix.

CALIFORNIA: San Francisco, July 12-15. Sec., Dr. Charles B. Pinkham, 906 Forum Bldg., Sacramento.

COLORADO: Denver, July 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

CONNECTICUT: Hartford, Reg. Bd., July 13-14. Sec., Dr. Robert L. Rowley, 79 Elm St., Hartford. Homeo. Bd., New Haven, July 13. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

DELAWARE: Wilmington, Regular Board and Homeo. Board, June 15-17. Pres., Dr. H. W. Briggs, Wilmington.

FLORIDA: St. Petersburg, June 14-15. Sec., Dr. H. M. Rowlett, Box 603, Tampa.

GEORGIA: Atlanta, June 9-11; Augusta, June 1-3. Sec., Dr. C. T. Nolan, Marietta, Ga.

INDIANA: Indianapolis, July 13-15. Sec., Dr. Wm. T. Gott, 421 State House, Indianapolis.

IOWA: Iowa City, June 8-10. Commissioner of Health, Dr. Don M. Griswold, State Capitol, Des Moines.

KANSAS: Kansas City, June 15. Sec., Dr. Albert S. Ross, Sabetha.

KENTUCKY: Louisville, June 24-26. Sec., Dr. A. T. McCormack, 532 West Main Street, Louisville.

MAINE: Augusta, July 6-7. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Baltimore, Reg. Bd., June 15-18. Sec., Dr. Henry M. Fitzhugh, 1211 Cathedral St., Baltimore. Homeo. Bd., June 15-16. Sec., Dr. Joseph S. Garrison, Old Orchard Rd., Ten Hills, Baltimore.

MASSACHUSETTS: Boston, July 13-15. Sec., Dr. Frank M. Vaughan, Room 144, State House, Boston.

MICHIGAN: Ann Arbor, June 8-10. Detroit, June 14-16. Sec., Dr. Guy L. Connor, 707 Stroh Bldg., Detroit.

MINNESOTA: Minneapolis, June 15. Sec., Dr. A. E. Comstock, 734 Lowry Bldg., St. Paul.

MISSISSIPPI: Jackson, June 24-25. Sec., Dr. F. J. Underwood, Jackson.

MISSOURI: St. Louis, June 28-July 1. Chief, Licensure, Dr. Ross Hopkins, Jefferson City.

NATIONAL BOARD OF MEDICAL EXAMINERS: Part I, June 21-23; Part II, June 22-23. All applications should be made on or before May 15. Sec., Dr. J. S. Rodman, 1600 Walnut Street, Philadelphia.

NEBRASKA: Omaha, June 8-10. Director, Bur. of Exam. Bds., Mrs. Clark Perkins, Lincoln.

NEW JERSEY: Trenton, June 15-16. Sec., Dr. Alexander MacAlister, Room 1101, Trenton Trust Bldg., Trenton.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 28-July 1. Chief, Mr. Herbert J. Hamilton, Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 21-25. Sec., Dr. K. P. B. Bonner, Morehead City.

NORTH DAKOTA: Grand Forks, July 6. Sec., Dr. G. M. Williamson, Grand Forks.

OHIO: Columbus, June 8-11. Sec., Dr. H. M. Platter, Columbus.

OKLAHOMA: Oklahoma City, June 15-16. Sec., Dr. J. M. Byrum, Shawnee.

OREGON: Portland, July 6-8. Sec., Dr. U. C. Coe, 1208 Stevens Bldg., Portland.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 6-10. Director Prof. Education, C. D. Koch, Harrisburg.

RHODE ISLAND: Providence, July 1-2. Sec., Dr. B. U. Richards, 315 State House, Providence.

SOUTH CAROLINA: Columbia, June 22. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Custer, July 20. Director, Med. Lic., Dr. H. R. Kenaston, Bonesteel.

TENNESSEE: Memphis, Nashville and Knoxville, June 11-12. Sec., Dr. Alfred B. De Loach, 434 Madison Ave., Memphis.

TEXAS: Austin, June 15-17. Sec., Dr. T. J. Crowe, 918 Mercantile Bank Bldg., Dallas.

UTAH: Salt Lake City, July 6. Dir., Mr. J. T. Hammond, 412 State Capitol Bldg., Salt Lake City.

VERMONT: Burlington, June 23. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 16-19. Sec., Dr. J. M. Preston, 720 Shenandoah Life Bldg., Roanoke.

WASHINGTON: Olympia, July 6. Director, Dept. of Licenses, Mr. Charles R. Maybury, Olympia.

WEST VIRGINIA: Martinsburg, July 6. Sec., Dr. W. T. Henshaw, Charleston.

WISCONSIN: Milwaukee, Basic Science Board, June 12-13. Sec., Dr. M. F. Guyer, Madison. Regular Board, June 29-July 1. Sec., Dr. Robert E. Flynn, State Bank Bldg., La Crosse.

WYOMING: Cheyenne, June 7-9. Sec., Dr. G. M. Anderson, Cheyenne.

Minnesota January Examination

The Minnesota Board of Medical Examiners reports the oral, written and practical examination held in Minneapolis, Jan. 5-7, 1926. The examination covered 15 subjects and included 80 questions. An average of 75 per cent was required to pass. Forty-three candidates were examined, all of whom passed. Six candidates were licensed by reciprocity and 2 by endorsement of their credentials. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
Stanford University School of Medicine	(1925)	89.8

Book Notices

A MANUAL OF THE PARASITIC PROTOZOA OF MAN. By Charles F. Craig, M.D., M.A., Lieutenant-Colonel, Medical Corps, U. S. Army, D.S.M. Cloth. Price, $7. Pp. 569, with 95 illustrations. Philadelphia: J. B. Lippincott Company, 1926.

Among workers in this country no one is better fitted by training and experience than Dr. Craig to write a useful, comprehensive and comprehensible work on the human parasitic protozoa. The friendly attitude with which one turns to an examination of the book is abundantly confirmed by its contents. The generous volume proves to be a mine of valuable information. One can hardly overemphasize today the importance of protozoan parasites in human medicine. The parasites of malarial fevers, amebic dysentery, trypanosomiasis, kala-azar, and various other even more recently discovered forms are recognized generally as among the most important causes of human disease. Yet it is hardly a generation since the epoch-making discoveries concerning the malarial organism and its transmission were announced, and at that time even the names of other organisms were mentioned rarely, if at all, in works on medicine. The extreme newness of the field makes it all the more difficult for a medical man to handle the material he may find, and if such a worker sought to orient himself in the general field, he would be compelled to depend, in large part at least, on publications in other languages than English. The present work summarizes an immense amount of accurate data concerning the various parasitic protozoa found in man. It introduces also those closely related parasitic forms from lower animals, the similar species of the coprozoic fauna and even the free-living types that have to be taken into account in accurate, differential diagnosis. While the work is definitely designed for the use of teachers, medical practitioners, students and health officials, and while it emphasizes very rightly the clinical significance of the various species and their definite relations to human disease, it is also reasonably well supplied with technical information of the zoological and biologic type. The author gives under each organism data concerning the correct name and the various synonyms, the history of the discovery and study of the organism, its structure, habits, reproduction, life history, distribution, the method of transmission, experimental infection and relation to disease, as well as the pathology, prophylaxis and diagnosis. At the end of each chapter is given in abbreviated form an admirable list of references to the important researches of recent date on the species in question. This list is reasonably complete from the standpoint of the original sources, and will be extremely valuable for all students of the subject. This feature is ordinarily entirely lacking in textbooks, and, even when present, is rarely if ever carried out with the care and completeness shown in this work. Considerable space has also been devoted to the methods of cultivating, staining and studying the various parasitic protozoa. Some of the illustrations are very fine; most of them are good, but a few are really illegible and, like figure 65, are even crude. A valuable feature in the treatment of the subject is the presentation of careful data concerning free-living species that are likely to be confused with parasitic organisms. The history of these early years in the study of parasitic protozoa is full of confusion that has arisen through accidental contamination of the material collected for examination. More than one form has been described like *Vahlkampfia lobospinosa,* which was "believed to be a dysentery ameba, but is a typical free-living species and is now known to have nothing to do with the etiology of dysentery" (p. 124). If Dr. Craig's effort accomplished nothing further than to prevent the recurrence of such confusion as has arisen in this and similar cases, all the time and effort put on the preparation and publication of this work would be amply justified as a contribution to scientific medicine. It is entirely natural to find the individual views of the author cropping out from point to point. Thus, one would find it difficult to secure general approval of the statement that "the production of symptoms by *Endameba histolytica* depends *entirely* on the lack of resistance of the infected individual to the infection" (p. 51). But why discuss such minutiae? In view of the great mass of valuable material which the author has brought together in this work, it will be many years before the subject is handled again by one of equal experience and ability. Indeed, Dr. Craig states that the material has accumulated during an experience of about thirty years in the study of these organisms and of about ten years spent in teaching the subject. On the whole, the treatment has been broad and fair and will commend itself to the careful student of the subject. Dr. Craig is to be congratulated on having produced a valuable work.

RÖNTGENBEHANDLUNG INNERER KRANKHEITEN. Von Prof. Dr. W. Parrisius, Privatdozent an der Med. Univ.-Klinik, Tübingen. Paper. Price, 15 marks. *Pp. 227, with 54 illustrations.* Leipsic: S. *Hirzel, 1926.*

The author first discusses the theory of the production of roentgen rays and the essentials of filtration. A section on the physical and biologic methods of measuring the rays leads to a chapter on deep dosage, in which appear the Holfelder patterns, which, placed on the body, locate the various organs and indicate the dosage. The clinical part of the book reviews the literature and presents the experience of the author. He quotes experiments establishing the fact that the hematopoietic organs are highly susceptible to the influence of the roentgen rays. The reaction of the blood and of the spleen is discussed. In chronic myelocytic leukemia, the author is convinced, no true cure can be achieved by radiotherapy. He cautions against it in acute cases, and even in chronic cases the dosage has to be chosen with extreme care. In lymphatic leukemia heavy doses are indicated, and roentgen-ray therapy has to be abandoned if the erythrocytes diminish. In lymphogranuloma there are occasionally favorable results; also in lymphosarcoma. Excisions for diagnostic purposes are not favored. In polycythemia rubra vera the author emphasizes the necessity of applying intense doses to the bones one by one so as to avoid injury to the large glandular organs by a flooding of the entire body with rays. Leukopenia is a danger signal With these precautions, some of the results are encouraging. In hemolytic icterus there were no convincing results, but irradiation is justifiable to provoke a hemolytic attack for diagnostic purposes. In localized tuberculosis, especially if the foci are on or near the surface, good results may be expected, though a direct bactericidal action of the rays cannot be established. In pulmonary tuberculosis, the rays accelerate the natural healing process. The stationary or slowly progressing cases and the cirrhotic and nodular forms respond to treatment. Caverns are not a contraindication, but all pneumonic exudative and acutely progressive forms are unsuitable for treatment. Only diminished doses should be employed. Tuberculosis of the larynx is amenable to treatment, provided there is no high fever and no accentuated tuberculosis of the lungs. In cases with deep ulcerations, irradiation is contraindicated. The dosage must be low, as heavy dosage produces edema, hoarseness and grave necrosis. The author does not favor irradiation in tuberculosis of the bones and joints. In bronchitis and bronchial asthma, no convincing results were reported. In cases of simple hypertrophy of the thymus, results have been satisfactory, but in complications ascribed to thymus disturbances, such as psoriasis or osteomalacia, the results are doubtful. The situation with regard to exophthalmic goiter is not clear, but irradiation in simple parenchymatous goiter is considered useless. No appreciable results were obtained on the suprarenals or pancreas. Roentgen-ray therapy in disturbances of the nervous system has produced a host of publications of contradictory character. Irradiation of prostatic hypertrophy may produce temporary results but cannot be brought in successful competition with surgery. Gonorrheal arthritis is the only form that seems to offer a favorable field. Reports on results in gastric ulcer are not encouraging. In glomerulonephritis, irradiation occasionally exerts a pronounced favorable influence on oliguria; but the operator should bear in mind that the skin of a patient with nephritis is very susceptible to roentgen-ray burns. Irradiation of the liver may produce late necrosis. The use of roentgen rays in tonsillar hypertrophy is not recommended. The closing chapter is devoted to a discussion of the general malaise that frequently follows roentgen-ray treatment.

Medical Diagnosis. For the Student and Practitioner. By Charles Lyman Greene, M.D., Chief of Staff, St. Luke's Hospital, St. Paul. Sixth edition. Cloth. Price, $12. Pp. 1468, with 723 illustrations. Philadelphia: P. Blakiston's Son & Co., 1926.

This edition is presented because of the rapid advances in many fields of medicine, both clinical and laboratory. The author begins with a fine plea for honesty and open mindedness in the practice of medicine, showing by many examples the errors and blind spots that may mislead us. Then follow chapters on history taking and external examinations, with pointers on estimating the value of evidence thus obtained. Following this, each system of the body is reviewed, with complete consideration of physical and laboratory findings and the diseases of this system. Thus follow excellent chapters on the basic facts of heart action with work, polygraph and electrocardiagraph, and all the other organs or systems are similarly treated. The volume is large and complete. For both student and medical practitioner it is admirably suited as either a reference work or as a volume for diligent study. Throughout there is much of an individual and personal note, and the reader feels that the author is making every effort to instruct him in such a way that he will not err in his conclusions. One rarely finds in a single volume the wealth of material here contained.

Handbuch der gesamten Augenheilkunde. Von Th. Axenfeld und A. Elschnig. Lieferung 488-490. I. Teil, I. Band, 2 Abt., Kapital III. Mikroskopische Anatomie der Regenbogenhaut. Von M. Wolfrum. Paper. Price, 16.50 marks. Pp. 218, with 57 illustrations. Berlin: Julius Springer, 1926.

It would scarcely seem possible that one could write more than 200 pages about the microscopic anatomy of that minute bit of colored tissue, the iris, without delving deeply into the physiology and comparative anatomy. Nevertheless, the author has succeeded in producing the most exhaustive purely anatomic description that exists in medical literature. The first fifty pages are devoted to the gross description of the iris, and include the clinical appearance as seen with the slit lamp of Gullstrand. Thirty pages are then given to the microscopic technic and method of collecting material for the microscopic study of the iris. The remainder of the book is a wonderful description of the histologic appearance of the iris, with magnificent illustrations, principally from the author's seemingly endless collection. The developmental phase and the comparative phase of the microscopic anatomy are touched on only when pertinent, and no undue attention is devoted to these. A bibliography of nine pages is appended. This is a book that should be read by every ophthalmologist and should occupy a handy place on his reference shelves. The printing and proof reading is on the same high plane as is the rest of the handbook; the illustrations are excellent, and the paper cover tears off easily.

Industrial Fermentations. By Paul W. Allen, M.S., Ph.D., Professor of Bacteriology and Head of Department, University of Tennessee. Cloth. Price, $5 net. Pp. 424, with illustrations. New York: Chemical Catalog Company, Inc., 926.

The primary purpose of this book is to correlate in a general way some of the present information on the application of micro-organisms to industry. The author states that he is making no attempt to treat the subject exhaustively, and, with the number of processes described—thirty-one—no other recourse would be possible in a book of this size. Mechanical steps having little to do with microbiology are described briefly, if at all. Fermentations are thus discussed: (1) prevention of undesirable changes, as in bottled and canned goods, drinking water and meat products; (2) reactions achieved by fermentation and not feasible by another process. as in the manufacture of bread; (3) reactions produced more economically than by other processes, as in the manufacture of alcohol. The author has included a great deal of original material, and each chapter is followed by a bibliography of the material consulted. In the description of some of the processes, one receives the impression that it would have been advantageous to include more of the mechanical operation. The type and magnitude of some of the apparatus employed in many of the fermentation industries is usually nothing short of marvelous to one who is accustomed to observe micro-organisms under the microscope. In discussing the method of determining the phenol coefficient, on page 71, a typographic error has been made. In the sentence which now reads "at the end of which time readings of growth or no growth are made and entered in a table as — or + signs, respectively," the signs should be reversed. Food preservation processes are fully discussed. The control of undesirable fermentations in the dairy industry has extensive treatment, and an account of the bacteriologic control of milk is included. Although many chapters in the book are concerned with the prevention of undesirable fermentations, the major part of the monograph is devoted to productive fermentations. There are numerous illustrations. The book is commended to those who would obtain a survey of the importance of fermentation, with particular emphasis on industrial processes.

The Natural Increase of Mankind. By J. Shirley Sweeney, M.A., M.D., D.Sc. Cloth. Price, $4. Pp. 185. Baltimore: Williams & Wilkins Company, 1926.

This work, which was Dr. Sweeney's thesis for his doctorate of science degree in hygiene at Johns Hopkins, is in chief part a statement of the problems of biometry and an introduction to the study of the scientific treatment of the factors that influence the trends of population. It is therefore not a popular treatise on the subject of population, but it is an interesting statement of the facts of population and the methods for their scientific treatment that have lately been emphasized. Altogether, it is a very informing book and can be commended to any one who is interested in this subject. Not the least interesting part is the introduction by Dr. William H. Welch, in which Dr. Welch, as always, is suggestive and in which he illustrates in this field the encyclopedic character of his scholarship. The increase of mankind is one of the fundamental problems of society in which medicine is involved. This book would furnish a good introduction for any physician who wishes to make a thorough study of the subject.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

Blood Chemistry: Colorimetric Methods. For the General Practitioner; with Clinical Comments and Dietary Suggestions. By Willard J. Stone, B.Sc., M.D., Attending Physician, Los Angeles General Hospital and Pasadena Hospital. Introduction by George Dock, M.D. Second edition. Cloth. Price, $3.25 net. Pp. 129, with 7 illustrations. New York: Paul B. Hoeber, Inc., 1926.

Technic and interpretation of laboratory tests with practical suggestions.

Human Physiology. By John Thornton, M.A. Revised by William A. M. Smart, M.B., B.S., B.Sc., Department of Physiology, London Hospital Medical College, University of London. Third edition. Cloth. Price, $3.75. Pp. 463, with 281 illustrations. New York: Longmans, Green & Co., Ltd., 1926.

British textbook of unusual brevity and little adapted to American curriculums.

Handbuch der praktischen Therapie als Ergebnis experimenteller Forschung. Herausgegeben von Reinhard von den Velden, A. O. Professor an der Universitat Berlin, und Paul Wolff, Dr. Med. et Phil., Berlin. Erster Band. Erste und Zweite Halfte. Paper. Price, 66 marks. Pp. 1137, with illustrations. Leipsic: Johann Ambrosius Barth, 1926.

First parts of a new and expansive German compilation on therapeutics.

The National Formulary. By Authority of the American Pharmaceutical Association. Prepared by the Committee on National Formulary of the American Pharmaceutical Association. Official from July 1, 1926. Fifth edition. Buckram. Price, $3.50. Pp. 545. New York: Chemical Catalog Company, 1926.

Newest edition of official manual for druggists.

The White Man in the Tropics: With Especial Reference to Australia and Its Dependencies. By R. W. Cilento, M.D., B.S., D.T.M. & H., Director, Australian Institute of Tropical Medicine. Commonwealth of Australia, Department of Health. Service Publication (Tropical Division) Number 7. Paper. Pp. 168, with illustrations. Melbourne, 1926.

Helpful hints for those tropically inclined.

Geschlechtskrankheiten bei Kindern. Ein ärztlicher und sozialer Leitfaden für alle Zweige der Jugendpflege. Herausgegeben von A. Buschke und M. Gumpert. Paper. Price, 5,40 marks. Pp. 108, with 10 illustrations. Berlin: Julius Springer, 1926.

Brief consideration of venereal diseases in children from medical and social points of view.

Talks to Nurses on Dietetics and Dietotherapy. By Ruth Wheeler and Helen Wheeler, The State University of Iowa. Cloth. Price, $1.50 net. Pp. 184. New York: W. B. Saunders Company, 1926.

Simple lectures for junior nurses, with especial reference to general principles rather than emphasis on details of individual diets.

Modern Methods in the Diagnosis and Treatment of Heart Disease. By Francis Heatherley, M.B., B.S., F.R.C.S., Superintendent Heart Clinic, Manchester. Second edition. Cloth. Price, $3.75. Pp. 269. New York: William Wood & Co., 1926.

Well written essays based on large experience in the school of Mackenzie.

A Manual of Normal Physical Signs. By Wyndham B. Blanton, B.A., M.A., M.D., Associate in Medicine, Medical College of Virginia. Cloth. Price, $2.50. Pp. 215. St. Louis: The C. V. Mosby Company, 1926.

An outline for students in physical diagnosis establishing the normal.

General Anæsthesia: A Text Book for Students and Practitioners of the Art of Anæsthesia. By Dr. James G. Poe, M.D., Lecturer on General Anæsthesia in the Medical and Dental Departments of Baylor University. Cloth. Price, $2.75. Pp. 150, with 7 illustrations. Dallas: The author, 1926.

Brief practical outline of technic by specialist in anesthesia.

A Joy Ride Through China for the N. A. C. By Cora E. Simpson, R.N. Cloth. Price, $3 Mex. Postage extra. Pp. 263, with illustrations. Shanghai: The Kwang Hsueh Publishing House.

A nurse's description of nursing in China.

Chininum Scriptiones Collectae anno 1924. Amsterdam: Bureau for Increasing the Use of Quinine, 1925.

Collected literature on quinine.

Health Hazards of Brass Foundries: I. Field Investigations of the Health Hazards of the Brass-Foundry Industry. II. Laboratory Studies Relating to the Pathology of Brass Foundrymen's Ague. By John Arthur Turner, Ph.G., M.D., Acting Assistant Surgeon, United States Public Health Service, and L. R. Thompson, Surgeon, United States Public Health Service. Prepared by Direction of the Surgeon General. United States Public Health Service, Public Health Bulletin No. 157. Paper. Price, 20 cents. Pp. 75, with illustrations. Virginia Sterilization Act Held Constitutional

(Buck v. Bell (Va.), 130 S. E. R. 516)

The Supreme Court of Appeals of Virginia says that the appellant, by her guardian and next friend, complained of a judgment of the circuit court by which Dr. Bell, superintendent of the State Colony for Epileptics and Feebleminded, was ordered to perform on her the operation of salpingectomy, for the purpose of rendering her sexually sterile. At the time she was committed to the colony she was 17 years old, had the mind of a child 9 years old, was the mother of an illegitimate child of defective mentality, and her mother had theretofore been committed to the same colony as a feebleminded person. Unless sterilized by surgical operation, she must be kept in the custodial care of the colony for thirty years, until she became sterilized by nature, during which time she would be a charge on the state. If sterilized under the law, she could be given her liberty and secure a good home, under supervision, without injury to society. Her welfare and that of society would be promoted by such sterilization.

The judgment complained of was rendered by the circuit court on an appeal from an order of the special board of directors of the colony directing that the appellant be sterilized by the surgical operation of salpingectomy, the superintendent of the colony having presented a petition for such order. The proceeding was strictly in conformity with the statute. But it was contended that the judgment of the court was void because the Virginia sterilization act was repugnant to the provisions of the state and federal constitutions in that it did not provide due process of law, imposed a cruel and unusual punishment, and denied the appellant and other inmates of the state colony the equal protection of the law. However, the act complies with the requirements of due process of law. An adjudication by an impartial tribunal, vested with lawful jurisdiction to hear and determine the questions involved, after reasonable notice to the parties interested and an opportunity for them to be heard, fulfils all the requirements of due process of law. Nor could the contention that the statute imposed cruel and unusual punishment be sustained. The act is not a penal statute. The purpose of the legislature was not to punish but to protect the class of socially inadequate citizens named therein from themselves, and to promote the welfare of society by mitigating race degeneracy and raising the average standard of intelligence of the people of the state.

Nor does the statute deny to the appellant and to other inmates of the state colony the equal protection of the law. It was not controverted that the state may, in proper cases, by due process of law, take into custody and deprive the insane, the feebleminded and other defective citizens of the liberty which is otherwise guaranteed them by the constitution. The right to enact such laws rests in the police power. Under statutes providing for compulsory vaccination, a surgical operation is performed, as in the instant case, for the good of the individual and of society. Such statutes, although they applied to school children only, have been upheld. It cannot be said that the act divides a natural class of persons into two, and arbitrarily provides different rules for the government of each. The two classes existed before the passage of the sterilization act. The female inmate, unlike the woman on the outside, was already deprived of the power of procreation by segregation, and must remain so confined until sterilized by nature, unless it is ascertained that her welfare and the welfare of society will be promoted by her sterilization under the act. There can be no discrimination against the inmates of the colony, since the woman on the outside, if in fact feebleminded, can, by the process of commitment, and afterward a sterilization hearing, be sterilized under the act. The court is of the opinion that the Virginia sterilization act is based on a reasonable classification, and is a valid enactment under the state and federal constitutions. The court has found no case involving similar statutes wherein the court has held that the state is without power to enact such laws, provided it be exercised through a statute that affords due process of law and equal protection of the laws to those affected by it. In the New Jersey case of *Smith* v. *Board of Examiners of Feebleminded, Epileptics, etc.*, 85 N. J. Law, 46, 88 Atl. 963, which this court declines to follow, the right to sterilize did not, as in Virginia, depend on whether the welfare of the patient would be promoted by the operation.

A Medical School Held Not to Be a Public Charity

(Hall v. College of Physicians and Surgeons (Mass.), 149 N. E. R. 675)

The Supreme Judicial Court of Massachusetts says that this action was in tort in two counts to recover damages for the conscious suffering and death of the plaintiff's intestate, alleged to have been caused by negligent medical care and treatment of the defendant's servants and agents while she was a patient, or by the negligent administration of certain drugs and medicines. The jury returned a verdict for the plaintiff on each count, and this court holds that the plaintiff was entitled to judgment on the verdicts, the action having been reported on the question of whether or not the defendant corporation was a charitable corporation within the intent of the law.

The defendant corporation was organized under "an act concerning associations for religious, charitable, educational and other purposes." The charter stated that the corporation was formed "for the purpose of establishing and maintaining a college for the prosecution and promotion of educational, scientific and medical purposes." A statute authorized and empowered it to confer the degree of doctor of medicine. The charter, however, did not of itself make the defendant a public charity. The controlling purpose must be for the common and public benefit, and if the defendant was created by the incorporators, or thereafter was administered and maintained by their successors for money-making, this essential element was lacking even if the defendant may at times have expended money for purposes, or rendered gratuitous services, which in common speech are called charitable. The defendant still would be acting within its charter powers if it charged every student in full for tuition, and clinical patients for medical care and treatment.

An announcement of the college stated that a limited number of suitable persons who gave satisfactory evidence of their inability to pay the regular college fees might be enrolled as students, and that it was hoped that as many friends of the college as were able would provide funds to aid deserving students. A physician who testified that he had general charge of the college, and his wife, who was its treasurer, were the principal witnesses. He testified that the college was in full operation in 1917, performing all the functions of a medical school, and that there was a dispensary—a corporation—which occupied part of the building in which the college was located, to which dispensary students of the college were assigned. The dispensary was advertised in the catalogue to make the college more attractive to students, and, while there was a great deal of charitable work done at the dispensary, three fourths of the patients were not charitable patients, and the remunerations of the professors were enhanced because of the dispensary, which was not conducted for profit. The income of the college was derived principally from fees of students, and in part from a trust fund under a will, with some minor donations. The college was educating men and women in the science of medicine and surgery, "just like other medical colleges, and sold nothing for profit." Tabulations of the treasurer for the years 1912 to 1917 showed only moneys received from students and payments to professors and instructors and to herself and her husband during that period. If, without deciding, it be assumed, as the defendant contended, that there was evidence that it was a public charity, yet the jury, under appropriate instructions, could find that the college was conducted primarily for the private ends of those who managed it.

Question Not Tending to Blacken Patient's Character

(Skruch v. Metropolitan Life Ins. Co. (Pa.), 131 Atl. R. 186)

The Supreme Court of Pennsylvania, in reversing a judgment obtained by the plaintiff on an insurance policy which the defendant company had issued in her favor on the life of her husband, says that the defendant alleged that the insured had given false answers to certain questions which were material to the risk, as that he had never had convulsions; and "affections, none." A physician who had attended him was asked to state whether or not he had treated the insured for epilepsy or convulsions. The trial court excluded the question because the physician had indicated to the court that the specific disease of which the insured was suffering was a loathsome one, of which epilepsy and convulsions were only symptoms. This ruling was based on the Pennsylvania act of 1907, which provides that no person authorized to practice physics or surgery shall be allowed, in any civil case, to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity, which shall tend to blacken the character of the patient, without the consent of the patient. But it is clear that, if a man has had convulsions and epilepsy, he has had them whether or not they were symptoms of some other disease. Yet the insured had denied that he had ever had them, and the question which was overruled was asked for the purpose of showing that he had thus made untrue answers in his application. Admittedly, a man may have had either or both of those complaints without this fact, if known, tending in any way to blacken his character. If the defendant, having received an affirmative answer to the question propounded, had then attempted to follow it up by an inquiry which, if answered, would have shown that the convulsions and epilepsy were symptoms of a loathsome disease, the act of 1907 would have been applicable, and an objection to the later inquiry would have been properly sustained. That, however, was not the question asked.

Second Conviction—Proof with Regard to License

(State v. Deadwyler (S. C.), 130 S. E. R. 332)

The Supreme Court of South Carolina, in affirming a judgment of conviction, says that it appeared from the testimony that the defendant was a chiropractor. On the first Monday in November, 1924, there were two indictments found against him for practicing medicine without a license. The first charged that he practiced on one Pruitt and other persons, Nov. 1, 1923, and divers other days before and after that date. The second indictment charged that he committed a like offense by practicing on one Bill Edwards and other persons, May 28, 1924, and on divers other days before and after that date. The defendant was tried at the November, 1924, term of court, was convicted, and served his sentence. He was put on trial at the summer term of 1925, under the second indictment. He demurred to the indictment, on the ground that the trial and conviction had at the November, 1924, term of court embraced all matters prior to that date, as to time and persons, and constituted a bar to the last indictment; but the demurrer was overruled, and conviction followed. The statute under which the indictments were brought provided that each day of its violation should constitute a separate offense; and this court does not agree with the contention that the use of the words "of divers other days before and after said date" embraced all of the time prior to the finding of the true bill under the indictment, and that the words "upon one Bill Edwards and other persons" embraced all persons up to such time, and that the conviction not only embraced the conviction for practicing on Pruitt, but on all other persons and at all other times prior to that date. The proving of the date of the commission of the act in this case was not material. It was only to allege with certainty the person on whom the defendant practiced. This was done by naming "one Bill Edwards," and this was sufficient.

Nor does the court agree with the contention that it was error to allow a member of the state board of medical examiners to testify, over objection, that the defendant had not obtained a license from the state board of medical examiners, the error alleged being that the witness was permitted to testify from his own knowledge, instead of producing the records of the board. The defendant said that it was incumbent on the state to show that he did not have a license. No question was raised as to the proof of the fact that he did practice on one Bill Edwards. It was made unlawful to do so, by statute, without having a license. This being so, while it was necessary to make the negative averment in the indictment, the act having been proved, it was incumbent on the defendant to show that he had a license. Even if the testimony of the member of the board should not have been admitted, the defendant could not complain. He knew whether he had a license and could have produced it, and he offered no testimony. But this court is of the opinion that there was no error in admitting the testimony of the member who testified that the defendant had not taken the examination of the board, had never appeared before the board, had not been granted any regular license to practice, nor granted a license to practice any specialty, such as chiropractic or osteopathy, or any separate part of the business of practicing; had never been granted any kind of license. This in no way altered the rule that the best evidence must be produced. One can always speak of his own knowledge of substantive facts within his knowledge. He must know the facts, and, knowing them, can relate them.

Unnecessary Averments in Indictment

(Robinson v. State (Ala.), 106 So. R. 203)

The Court of Appeals of Alabama, in affirming a judgment of conviction of defendant Robinson, says that the indictment in this case was returned at the January, 1922, term of the circuit court, and that the trial thereunder was held in February, 1925. The indictment charged the defendant with the offense denounced by section 7564 of the code of 1907, as amended in 1915, which prohibits any person from treating or offering to treat diseases of human beings without having obtained a certificate of qualification from the state board of medical examiners. The only question presented on this appeal was the action of the trial court in overruling demurrers to the indictment. All that is necessary in an indictment properly to charge this offense is:

> The grand jury of said county charge that, before the finding of this indictment, A. B. (naming the defendant) did treat or offer to treat diseases of human beings in this state without having obtained a certificate of qualification from the state board of medical examiners, against the peace and dignity of the state of Alabama.

Such averments in the indictment as were here contained, namely, by a system known as chiropractic for a reward, are not necessary to a valid indictment. As stated, the offense denounced is treating, or offering to treat, human diseases, without a certificate of qualification from the state board of medical examiners; and, the quoted averment, "by a system known as chiropractic for a reward," is not an element of the offense. The phrase in the statute, "by any system of treatment whatsoever," is no part of the description of the offense. However, as to the unnecessary averments, above mentioned, in the indictment in the case at bar, they in no manner vitiated the indictment. They very probably subjected the indictment to proper demurrer, but the demurrers interposed here did not raise the question. The demurrers that were interposed to the indictment were properly overruled.

Society Proceedings

COMING MEETINGS

American Ophthalmological Society, Hot Springs, Va., June 14-16. Dr. Emory Hill, Professional Building, Richmond, Va., Secretary.

American Orthopsychiatric Association, New York City, June 5-6. Dr. Karl A. Menninger, Mulvane Building, Topeka, Kansas, Secretary.

American Psychiatric Association, New York City, June 8-11. Dr. Earl D. Bond, 4401 Market Street, Philadelphia, Secretary.

American Psychopathological Association, New York City, June 11. Dr. Sanger Brown II, 173 East 70th Street, New York City, Secretary.

American Therapeutic Society, Philadelphia, June 10-12. Dr. W. J. Mallory, 1720 Connecticut Ave., N. W., Washington, D. C., Secretary.

Associated Anesthetists of the United States and Canada, Nottingham, England, July 20-23. Dr. F. H. McMechan, Avon Lake, Ohio, Sec'y.

Maine Medical Association, Poland Springs, June 10-12. Dr. B. L. Bryant, 265 Hammond Street, Bangor, Secretary.

Massachusetts Medical Society, Springfield, June 8-9. Dr. W. L. Burrage, 182 Walnut Street, Brookline, Secretary.

Medical Library Association, Ann Arbor, Mich., June 8-9. Miss Harriet Wilson, 535 North Dearborn Street, Chicago, Secretary.

Montana, Medical Association of, Billings, July 16-17. Dr. E. G. Balsam, 222 Hart-Albin Building, Billings, Secretary.

National Association for the Study of Epilepsy, New York City, June 7-8. Dr. A. L. Shaw, 108B The Albiston, Utica, N. Y., Secretary.

New Jersey, Medical Society of, Atlantic City, June 17-19. Dr. J. B. Morrison, 97 Halsey Street, Newark, Secretary.

North Carolina, Medical Society of the State of, Wrightsville Beach, June 15-17. Dr. L. B. McBrayer, Southern Pines, Secretary.

Oklahoma State Medical Association, Oklahoma City, June 22-24. Dr. C. A. Thompson, 609 Barnes Building, Muskogee, Secretary.

Wyoming State Medical Society, Lander, July 12-13. Dr. Earl Whedon, Sheridan, Secretary.

ASSOCIATION OF AMERICAN PHYSICIANS

Forty-First Annual Meeting, held at Atlantic City, N. J., May 4-5, 1926

Dr. Richard P. Strong, Boston, in the Chair

Heart Disease in New England

Drs. Paul D. White and T. Duckett Jones, Boston: Nearly 3,000 cases have been tabulated. A striking feature was the high incidence in persons under 20 years of age, seen in hospital practice; this is largely due to admissions for rheumatic infections. In private practice the incidence is among older persons. In consultation cases there is a high incidence of functional disorders among elderly persons. In hospital cases, rheumatic disease forms a very high incidence, 49 per cent; in the three groups together the incidence is 41 per cent. Bacterial endocarditis is equally divided among the three groups. The hypertensive and the arteriosclerotic groups constitute about 51 per cent of the total series. The coronary occlusion group seems more frequent among consultation cases, as a result of the higher age incidence of the consultant's patients, and also of more careful histories. The figures for syphilitic disease seem rather low in New England (4 per cent), as compared with those quoted for New York. The congenital rate is high in the hospital series, because many syphilitic children are referred for treatment. Cases classified as unknown form 2.5 per cent of the total series. Angina pectoris runs higher in the consultant series. The total percentage of angina pectoris in all forms of disease is 15.9. Effort syndrome constitutes 47 per cent of the functional conditions. Functional systolic murmurs are most often seen in children. Of the organic lesions, chiefly rheumatic cases, mitral lesions form 24 per cent; aortic, 2.3 per cent; mitral with aortic, 13.5 per cent, and pericarditis 2.7 per cent. Aneurysm is rare, only 0.7 per cent; flutter is also rare, 0.2 per cent of all lesions. More than one condition is often present in the same patient.

DISCUSSION

Dr. J. S. McLester, Birmingham, Ala.: I should like to point out the relative infrequency of rheumatic fever in the South. We see very few rheumatic hearts as contrasted with the figures given by Dr. White. If I could hazard a guess, the number would be nearer 10 per cent.

Dr. W. S. Thayer, Baltimore: After a study of thirty-six years in the Johns Hopkins Hospital, I do not think there is so great a difference in the frequency of occurrence of angina pectoris among hospital patients, or a change in the manner of life and of the class; but there is a great difference in the care with which patients are interrogated and the way in which the symptoms are evaluated and the diagnosis made on the way in which the patient describes his symptoms. A large number of patients cannot give an intelligent account of their symptoms, but if one interrogates them with very careful questioning so as to get a history of anginoid symptoms, one finds a surprising number of cases. That explains the increase in angina, rather than a great difference in the class of patients. Angina from the standpoint of the anatomic changes is, I fancy, not much more frequent today than it was thirty years ago. I think we have seen very much more angina in recent years in hospitals because we have looked for it. It is hard to get a colored patient to give an intelligent account, but if questioned carefully one finds he has the characteristic symptoms.

Dr. Lewis A. Conner, New York: There is one point that the speaker mentioned which deserves emphasis in the discussion. In contrasting rheumatic and syphilitic cases of aortic insufficiency, he noted that syphilitic insufficiency was slightly larger than purely rheumatic insufficiency. There is a widespread misconception as to the relative frequency of these conditions. The rheumatic type in the hospital series is under 2 per cent and the syphilitic type over 2 per cent. The rheumatic type associated with mitral disease is 15 per cent. I am convinced that in our gradually increasing emphasis on syphilitic cases of aortic insufficiency we are swinging too far. Students get the impression that the syphilitic type of aortic insufficiency is much more common in adults than the rheumatic type. I think that is entirely wrong. While rheumatic cases may be less frequent in the hospital wards, they are not such an acute condition that physicians in the wards do not see them. They are apt to be seen in the outpatient department rather than in the ward.

Dr. Joseph Pratt, Boston: My own series of case results are similar to those presented in the paper. In 312 cases of organic heart disease seen in the hospital, there were five cases of syphilitic origin. The Wassermann test was done regularly, and the aorta was examined with the fluoroscope. These figures, however, are a contrast to studies by other observers in private practice. When I was in the South I made an intensive study in Georgia and Alabama and I was impressed with the great rarity of rheumatic heart disease, especially of mitral stenosis; but there were many cases of syphilitic heart disease among negroes.

Dr. Harlow Brooks, New York: I was surprised that so few cases of syphilitic mitral stenosis were recognized, and also syphilitic angina pectoris, as this is very frequent. I think that if the figures are higher in New York it is not on account of the greater moral obliquity there, but because of the fact that we are rather apt to exchange cases and to send patients to men who are particularly interested in them, so that some cases are rather overestimated and some underestimated; that is true of cases of syphilitic heart disease if we rely solely on the Wassermann reaction, which is often misleading. I believe that the history and clinical findings are much more reliable in these cases.

Dr. T. Duckett Jones, Boston: Aortitis may occur with or without cardiac involvement. There are a number of angina pectoris cases in the syphilitic group, but they are included with other diagnoses. It was impossible in the time allotted to analyze the cases more fully, but this material will be given in the more detailed report to be published.

Relation of the Toxemias of Pregnancy to Hypertensive Cardiovascular Disease

Drs. W. W. Herrick and Jean Corwin, New York: The disease called toxemia of pregnancy includes a very miscellaneous group of symptoms, such as pernicious vomiting, visceral disturbance, toxic jaundice and severe anemia, so that a study of disturbance of a single organ would be inadequate. We have applied another type of study and have taken the antenatal period as well as a follow-up study lasting from three months to six years, making a postpartum study of some women through successive pregnancies. The subacute type with hypertension forms the largest group; these women show a blood pressure of about 180, albuminuria, edema, oliguria, perhaps mental symptoms, and often death of the fetus. Often with the delivery of the fetus the symptoms clear up. The blood chemistry often shows increase of uric acid and cholesterol. There are frequent cardiovascular changes with tortuosity of the retinal arteries, often hemorrhages and white spots in the choroid. We have followed up 165 cases of this subacute type for a prolonged period and have classified them according to their blood pressure, anything over 140 being considered hypertensive. As the blood pressure rises, the number of cases showing displaced apex is increased, and 50 per cent of hypertensive cases show retinal changes. The status of the blood pressure is important. After delivery it will often return to normal, but after a few months or years it goes back to above normal. In a summary of blood pressure readings it was shown that from 71 to 100 per cent had persistent hypertension, according to the severity of the previous blood pressure rise. These cases, which are of mild type, and frequent, merit more attention from the obstetrician because, if followed up, they later show definite organic cardiovascular changes. These women represent a class of substandard cardiovascular make-up, who react to the strain of pregnancy as do others to the wear and tear of daily life.

DISCUSSION

Dr. W. S. Thayer, Baltimore: In what proportion of these patients were you able to obtain a history of what the condition was before the onset of symptoms with undisguised eye changes?

Dr. Joseph L. Miller, Chicago: The average obstetrician does not think of later consequences. I have a series of cases in which the pressure was taken previous to pregnancy, and the hypertension was persistent over several years.

Dr. J. P. O'Hare, Boston: What was the evidence that there was not any previous kidney disease, because retinal arteriosclerosis indicates previous hypertension in 95 per cent of cases? It takes a certain length of time—at least five years—for retinal arteriosclerosis to develop.

Dr. W. W. Herrick, New York: Many of these cases have a long standing history of cardiovascular disease if followed through previous pregnancies. We can predict what will happen. The patient with cardiovascular disease reacts in this way with hypertension and albuminuria. As regards prognosis, we cannot be very definite. Thirty-seven per cent reacted with persistent hypertension, and 64 per cent showed changes of various kinds. I think pregnancy is a test of the maternal organism. Probably these patients react to the wear and tear of pregnancy as they finally will react to the wear and tear of life.

Treatment of Attacks of Syncope Occurring in Adams-Stokes Disease

Dr. Samuel A. Levine, Boston: The symptoms of Adams-Stokes disease are characterized by congestive heart failure and very slow heart rate. This may be as low as 20, which is too slow, but with a rate of 35 the patient may be able to be physically active. Patients also suffer from syncopal attacks which may end fatally. To treat these attacks is important in persons who would otherwise be fit. Some patients have attacks every hour or even as often as every ten minutes. If the patient has syncope with complete standstill of the heart, intravenous injection is useless because the drug does not circulate. What method have we for further prevention of these attacks? Barium chloride by mouth, 30 mg. four times daily, apparently has a favorable influence. It is an irritant of the vagus and thus stimulates the heart beat.

DISCUSSION

Dr. Paul D. White, Boston: One patient was relieved by barium chloride for several months. Then there was a recurrence of the attacks, and barium chloride was not effective. After that epinephrine was used with good effect

Dr. Frank N. Wilson, Ann Arbor, Mich.: During the last year three patients have died of Adams-Stokes disease at Ann Arbor. Two received epinephrine directly after death but neither patient was revived. One case was similar to that quoted by Dr. Levine. The attack lasted fifty-five seconds. The heart was made to beat by striking the precordium, and normal rhythm returned.

Dr. S. A. Levine, Boston: The routine therapy in our cases was to give epinephrine thirty minutes subcutaneously, 0.5 cc. of a 1:1,000 solution. The combination of barium chloride with epinephrine increased the irritability of the ventricle.

Effects of Hepatic Extract on Arterial Hypertension

Dr. Ralph H. Major, Kansas City, Mo.: We have made a study of various metaboloids. Guanidine produces a marked, sustained rise of blood pressure, the same as that obtained in arterial hypertension. We have studied hypertension and possibly the means of removing it by producing a substance capable of counteracting guanidine hypertension. Liver extract is very helpful. Histamine gives a different result. To show this it was necessary to procure pure liver extract free from the histamine and choline content. We tried the effect of liver extract on patients suffering from hypertension. We found that patients vary in their response, and that the same patients will vary from time to time. The results in patients confined to bed have been less satisfactory, perhaps because the dosage was too small; perhaps because there was considerable arterial injury. The best class of patient would be the young person with hypertension just beginning.

DISCUSSION

Dr. B. S. Oppenheimer, New York: We have given pure liver extract, freed from histamine and choline, in cases of essential hypertension, with a systolic pressure of 200 or over and a diastolic pressure of 100 or over. At first we had some good effects with the first lot of preparations used; lately we have had no effect. Perhaps the explanation is that the blood pressure reducing substance is unstable.

Dr. J. S. McLester, Birmingham, Ala.: We have been working on guanidine bases and have observed the effects of liver extract on a certain group of patients under 45 years, with early hypertension. Our results have been favorable. We frequently saw a drop following its use, lasting many hours, and occasionally we saw improvement with relief from the headache which did not respond to other measures. In a few instances we saw mild shock and dizziness, but we could not see any lasting effect on the blood pressure.

Dr. Lewis A. Conner, New York: In what percentage of the cases tested with liver extract were such striking results obtained as those recorded on the last chart shown? What proportion of the cases showed any results?

Dr. J. P. O'Hare, Boston: One fact stressed by Dr. Major should be emphasized, and that is that the preparation must be absolutely fresh. Another point to be noted is that Dr. Major has used very large doses by comparison with other workers. At the Peter Bent Brigham Hospital we have used smaller doses, but the results have not been entirely satisfactory. In two cases out of seventeen there was effect; in fifteen cases there was not any effect. We have never had a preparation that was absolutely good. If we could be certain of the stability, the results might be different.

Dr. H. O. Mosenthal, New York: We have had the same results as those reported by Dr. McLester and Dr. Oppenheimer, but in two out of fifteen cases treated the results have been very gratifying. One blood pressure came to the normal level from 200, and in another case the blood pressure came down and the symptoms subsided. I feel very strongly that Dr. Major has a preparation which, when properly handled, is going to relieve hypertension and relieve a disease that is extremely widespread. I think that the experimental evidence at hand shows that the preparations we have been receiving are not stable.

Dr. Ralph H. Major, Kansas City, Mo.: In regard to Dr. McLester's remarks: we have been very much impressed with the relief of headache, tinnitus, dizziness and other disagreeable symptoms. Of course, the psychic element is hard to rule out, but the results are very striking and cannot be explained entirely by the psychic effect. We started by trying to give uniform dosage, with little result; then we tried giving a dose that would reduce hypertension, and we gave 15,000 units a day as standardized against guanidine. In regard to the percentage of response, that is a difficult question to answer. There is a great deal of personal equation in the question as to whether there is response. When the patient gives a response, one does not know whether it is spontaneous or not. We have one woman whose pressure goes down following dosage, but we do not know whether this is a response to the drug, or whether she has a cycle of hypertension. Cases must be observed for a much longer time before we can make any statement as to the result.

Leukemoid Blood Pictures

Dr. E. B. Krumbhaar, St. Louis: We have made a study of blood pictures in nonleukemic cases which resemble the blood picture of leukemia cases, some cases very closely approaching the leukemia slides. In two cases there was a lymphocytosis of 75 per cent during an acute infection. In another case, a chronic carcinoma of the breast, the leukocytes numbered 120,000, with 92 per cent polymorphonuclears. Some of these cells are immature forms. The diagnosis was never in doubt, but if it had been made from the blood picture alone it would be thought to be myeloid leukemia. In a case of gas poisoning, the blood count fell and then rose, the rise being due to myelocytes. Such reactions have also been seen in cases of acute pelvic infection in women. Emphasis should be placed on the extreme length to which some of these reactions may go, and the atypical nature of them; also the difficulty of making a differential diagnosis from leukemia if the blood picture alone is taken into consideration.

Pulmonary Changes Following Artificial Hemoptysis

Drs. Charles R. Austrian and H. S. Willis, Baltimore: It is a matter of clinical observation that the roentgen-ray shadows of lungs of patients often show mottlings which later disappear. It would seem that there are two types of tuberculosis, those in which it progresses with the course of the disease, and some that go on to healing, the shadows being due to collateral inflammation or healed tubercles, or to an exudative lesion, as is seen in animals with healed tubercles when a tuberculous infection is added. In experimental animals previously infected we were not able to produce diffuse miliary tuberculosis, but the lesions were an exudation of leukocytes and serum due to sensitization on the part of the animal from previous infection. I believe that in hemoptysis in the human being, due to an existing allergy, the shadows are often due to collateral inflammation about the site of lodgment of the bacilli. In these cases there is a more favorable prognosis than is usually given.

DISCUSSION

Dr. Homer F. Swift, New York: Were the tuberculous animals injected with blood plus tubercle bacilli? I believe that in tuberculous tissues there is a substance which, when added to tuberculosis, is more irritating than the bacilli alone. In hemoptysis I think it is due to that state of affairs rather than normal blood going into the lung.

Dr. Charles S. Austrian, Baltimore: We have used blood of tuberculous rabbits with tubercle bacilli, and also blood alone and we have seen no difference in the reaction. For that reason we used normal blood with bacilli rather than blood of infected animals. Whether there is any difference in the speed of reaction I am not prepared to answer. The test rabbits were infected by bovine tuberculosis. We had two groups, normal rabbits and infected rabbits. They were injected intratracheally with suspension of tubercle bacilli in normal blood. In the first group the roentgenogram did not show as much disease as was demonstrated at necropsy.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

Appendicitis in Children Under Five Years of Age. F. Christopher, Winnetka, Ill.—p. 525.

Biliary Cirrhosis.—A case of biliary cirrhosis is described by Parsons and Hickmans in which there was evidence of obstruction of the bile ducts, but not in their extrahepatic course. The argument is brought forward that this case supports the view that the hepatic cirrhosis occurs in at least as early a stage of this disease as the changes in the bile ducts. Metabolism balance experiments show that: fat is well split; there is an increased formation of fatty acid; fat absorption is poor; nitrogenous absorption is good; there is a negative balance for calcium, and phosphorus absorption is good; a very great proportion of the excretion of phosphorus is via the urine. The presence of large quantities of unabsorbed fat in the intestine—due to the exclusion of bile—resulted in a negative calcium balance, and a deviation of phosphorus to the urine, but had no effect on the absorption of nitrogen.

Chronic Interstitial Hepatitis.—A case of chronic interstitial hepatitis occurring in an infant, aged 11 months, the first sign of which appeared on the eighteenth day, is reported by Munns. The etiologic agent could not be determined. Possibly, there was a slow infectious process, as evidenced by exacerbations and remissions in the signs and symptoms, particularly the frequent and intermittent rises in temperature.

Death Caused by Inhaling Zinc Stearate.—Schlaepfer reports the case of a child, aged 7½ months, who died thirty-four hours after inhaling zinc stearate. Cyanosis and dyspnea characterized the clinical course of the illness, and a state of "acidosis" was noted twelve hours before death. At necropsy, the lungs were voluminous. Extensive areas of emphysema were separated from each other by small, scattered, atelectatic zones. The bronchioles contained plugs of zinc stearate and mucus, which appeared as wormlike masses. The gross picture was confirmed histologically, and the presence of extensive edema was determined. The edema involved the alveoli, especially the more atelectatic ones, and the subpleural and interlobular connective tissue septums. The lymphatics throughout the lung were conspicuously dilated. In spite of oxygen inhalation, persistence of the dyspnea may have been due to acidosis brought about by incomplete obstruction to the bronchioles with zinc stearate.

Syphilitic Endarteritis in Children.—One of the patients seen by Gilkey and Dennie was a colored girl, aged 3 years. The entire dorsum of the right foot was of a bluish hue. The three middle toes and the ends of the great toe and little toe were black. On the plantar surface of the foot there was a large black bleb, extending about 2 inches backward from the three middle toes. The second patient was a Mexican girl, aged 3 years. She had a large ulcer on the outer aspect of the right leg, extending from the external malleolus for one-third up the leg. Each patient received the same type of treatment, namely, 0.15 Gm. of neo-arsphenamine, intravenously, every week for eight weeks. Potassium iodide was given internally. Both patients recovered promptly, but the first patient lost two toes.

Erythema Infectiosum.—The evidence presented by Herrick indicates that the disease is a distinct entity, is infectious, and results in the establishment of a specific immunity. The distinguishing features of the disease are its occurrence in epidemics, the lack of constitutional symptoms, the lack of any features distinctive of the other exanthems, the long course and characteristic progression of the rash, its evanescence at all stages, and particularly the irregular but brilliant outlines seen on the arms and legs in the third stage and in the recurrences.

Uric Acid and Creatinine Excretion of Infants.—The uric acid excretion per twenty-four hours was measured by Rougichitch in a series of twenty-two male infants. The diet of the infants being purin free, the amounts of uric acid are regarded as of endogenous origin. In contrast with most of the hitherto published measurements of uric acid in infants' urine, a closely constant daily excretion was found for the individual, and a fairly constant value per unit of body weight for the group of infants, the range being from 14 to 25 mg. of uric acid per kilogram of body weight. Except in the case of an infant with active rickets, whose uric acid excretion was high (36 and 34 mg. per kilogram of body weight) no relationship of nutritional state to uric acid excretion was apparent. Uric acid excretion was also apparently independent of the age of the infant. It is suggested that the relatively high level of endogenous uric acid by infants may be explained by their high protein intake. Measurements of urine creatinine in the same group of infants support the conception of a close constancy of creatinine excretion in terms of the protoplasmic mass of the body. The range found was from 10 to 15 mg. per kilogram of body weight. The highest values were obtained in malnourished infants, probably because of their relatively larger mass of active tissue. No relationship of creatinine to differences in sleeping time or no muscular tonus was discernible. However, in the case of an infant having severe generalized convulsions, a creatinine excretion three to four times higher than normal was observed. Another infant with slight localized convulsions was found to excrete an approximately normal quanity of creatinine.

Determination of Urea and Ammonia Nitrogen of Saliva.—The method described by Schultz and Ziegler is a modification of that for the determination of blood urea described by Folin. The values obtained by its use are said to approximate those of blood-urea nitrogen more closely than do the results afforded by any other published method.

Paratyphoid in Infant.—A case of paratyphoid fever in an infant, aged 18 months, is reported by Gingold and Wexler. The salient clinical features were persistent abdominal pain of three months' duration, marked secondary anemia, a relatively brief febrile period, and isolation from the blood of *Bacillus paratyphosus* B.

*Renal Sepsis Associated with Manic Depressive Insanity. E. F. Kilbane, New York.—p. 433.

Mortality of Splenectomy.—Mayo says that if a patient is properly rehabilitated and on the up-grade, the result of proper methods of preparation, the mortality of splenectomy will be less than 5 per cent. The dangers of the operation are largely in delay and in an unfortunate choice of cases.

Acute Leukemia and Infectious Mononucleosis.—A case of acute leukemia is reported by Schenck and Pepper, of the lymphatic or lymphoblastic type, in which, during a remission perhaps induced by treatment, the blood picture passed through stages at which it closely resembled infectious mononucleosis and even reached the stage where it resembled the picture of agranulocytic angina. A rapid return of the leukemic blood picture, however, followed with fatal outcome.

Detection of Positive Centrifugal Venous Pulse.—It is suggested by Middleton that the simple procedure of elevating the arm may establish the presence of a positive centrifugal venous pulse in the radial vein in cases of relative tricuspid insufficiency, and that this phenomenon is not observed in normal controls or in any conditions under which the ventricular type of venous pulse has been described, other than tricuspid insufficiency.

Raynaud's Disease with Bone Involvement.—Monahan reports a case of Raynaud's disease which showed few of the classic Raynaud phenomena and in which parts of the body skeleton of the foot were sloughed out in a discharge (corresponding no doubt to the "seropurulent liquid" mentioned by Raynaud), which was found on examination to be sterile. Postoperative dissection showed a remarkable adaptation of the crippled foot to the demands made on it by change in position for weight bearing.

Response of Normal Stomach to Foods.—The result of this research by Hawk et al. shows that there is a certain characteristic response of the stomach for each variety of foodstuff. The results also serve to emphasize the ability of the normal stomach to satisfactorily handle a great variety of foods. In each particular instance, the stomach has a certain amount of work to do which in health it does in a highly characteristic manner. The digestion of meats is of great interest, and the same thing is true regarding the digestion of fresh vegetables. With the raw vegetables, however, digestion is much more of a mechanical procedure, but in each instance the test of a normal stomach is the ability of that stomach to handle these substances in characteristic fashion. In experiments it was apparent that functional diseases almost resulted in either a delay in evacuation or in a rise in the acid secretion or, again, in a failure of the stomach to react rapidly to the food in question.

Incipient General Paralysis.—A study of the earliest symptoms which may occur in patients who later develop outspoken general paralysis was made by Bunker in seventy-four cases. He found that irritability occurred as the earliest abnormality, or one of the earliest, in forty-two cases. The character change, whereby an individual is reduced in activity and spontaneity, loses some of his interests, tends to withdraw into himself, and is often described as having become "quiet," is likewise a common early symptom, for it occurred in twenty-eight cases. Loss of weight ranks as third. It occurred—and very often early—in twenty-two cases. An increased tendency to sleep was an early manifestation in fifteen cases. Speech defect, memory defect and judgment defect have considerable diagnostic value in themselves, but occurred among the earliest symptoms in only eleven, fifteen and seven cases, respectively. Visual impairment, digestive disturbance, insomnia, fatigability, headaches, tremor, and rheumatoid pains were present as the earliest manifestations in a few cases.

Alcoholic Injections into Nerves Relieve Pain.—Alcoholic injections into nerve tissues for the relief of pain has proved a valuable therapeutic procedure in Swetlow's experience. In five cases of pulmonary tuberculosis with pleuritic pain, Swetlow injected those intercostal nerves whose skin areas were hyperalgesic to pin prick. The patients have been relieved from their pain since the injection, that is, from thirty-five to 107 days. In three cases of headache the involved nerve was injected with successful results; likewise, in one case of tabes with crisis. In one case of pain in cardiac disease, paravertebral injections of alcohol gave relief. In a case of pruritus ani the introduction into the epidural space of a 20 per cent solution of alcohol in saline solution was followed by immediate and lasting relief.

Function of Autogenous Kidney Transplant.—Ibuka reports on the successful experimental transplantation of kidneys into the neck of dogs. The transplanted kidney functions for months in a practically normal manner, coexisting with the normal kidney in the abdomen; it also maintained the life of the animal in good health for a fairly long time after the excision of the other kidney, while preserving its own functional activity. One transplanted kidney was in good condition four months after the removal of the other kidney. Analysis of chemical constituents of urine from the transplant, as well as various functional tests made on it, simultaneously with the investigation of the remaining kidney in the abdomen or after the removal of this sister organ, showed a fairly normal kidney function. An apparently compensatory activity of the transplant was observed after ablation of the other kidney. The extrinsic nerve supply to the kidney and the ureter, Ibuka says, plays a minor and unessential part in their function, as the transplanted kidney functions equally well in the new location, and the renal pelvis and ureter show even an increased peristalsis. The ultimate failure of the function of these autogenous kidney transplants, which have been transplanted successfully in the neck and have functioned a fairly long while, seems to be caused by hydronephrosis and infection, mainly incurred by mechanical insult in the new location.

Function of Homogenous Kidney Transplant.—Homogenous transplantation of the kidney was performed and studied by Ibuka in fourteen pairs of dogs. The function of the homotransplants in the neck was found to continue for a few days (an average of three days) after transplantation and to end by necrosis or softening of the transplant shortly after the cessation of its function. Chemical analysis of specimens of urine and functional tests on the transplanted kidney proved that the homotransplant functioned similarly to the autotransplant for a limited time, but the function soon changed and finally ceased.

Septic Kidney and Manic Depressive Insanity.—Kilbane reports on a case of calculus pyelonephritis in a patient suffering also with a serious mental disturbance. No other gross focus of infection was apparent, and while sepsis may not be accepted generally as a cause of manic depressive psychosis, it seemed reasonable to Kilbane to suppose that the kidney condition might be in this instance an important etiologic factor.

Surgery, Radium and Roentgen Rays in Treatment of Carcinoma of Cervix. H. H. Bowing, Rochester, Minn.—p. 400.

Shock in Pregnant and Puerperal Women.—Bailey and Driscoll treat shock in the following manner: In patients exhibiting preliminary symptoms of shock and exhaustion, no operative procedure should be considered until the blood pressure is 100 or above, and the operation should be conducted under gas and oxygen anesthesia, three parts to one. One should be prepared to encounter shock in the delivery of patients. After acute hemorrhage a mechanical packer should immediately be inserted into the uterus and the uterine cavity packed with iodoform gauze. Usually it is well to pack the vagina also. In the presence of actual shock, the patient should be placed with the head and shoulders lower than the rest of the body and given warm tap water by rectum, 6 ounces (180 cc.) at a time. One thousand cubic centimeters of physiologic sodium chloride solution should be injected by hypodermoclysis beneath the breasts. If the shock is complete and the blood pressure is 80 or below, 300 cc. of gum-glucose solution should be injected slowly, at the rate of 3 or 4 cc. per minute. A universal donor should be brought to the hospital, and if the blood loss has been excessive, transfusion should be done.

Use of Vaginal Stethoscope in Early Diagnosis of Pregnancy.—To promote the hearing of the fetal heart tones before the eighteenth week, Falls devised a stethoscope that could be applied over the lower uterine segment through the vagina. This was accomplished by making a long-handled stethoscope, the bell of which could be introduced into the vagina, and the earpieces attached to the rubber tubes of an ordinary Shepherd stethoscope. He has been able to diagnose pregnancy at about the fourteenth to sixteenth week in twenty patients. Another use to which the vaginal stethoscope may be put is the auscultation of the lower uterine segment in patients with placenta praevia. At or near term there is audible a uterine souffle on both sides of the midline in the lateral fornices in normal cases. However, this normal uterine souffle was decidedly increased, noticeable even in the early months, in two patients with low implanted placenta.

Manual Intra-Uterine Rotation of Fetus.—Analysis of 2,000 obstetric cases made by Smith shows that manual intra-uterine rotation of the fetus in eighty-two selected cases, whereby the position was changed from occipitoposterior to occipito-anterior through an arc of 180 degrees, does no harm to the mother and only rarely jeopardizes the child. It is of great benefit to mother and child because of the shortening of labor and because of the diminution of trauma when the labor is terminated.

Chancre of Cervix.—Cron is of the opinion that the primary lesion of syphilis occurs frequently on the cervix, and that its apparent rarity is due to the fact that it is frequently overlooked and that it rapidly involutes.

Full Term Extra-Uterine Pregnancy.—LeDoux reports three cases. One was an ovarian pregnancy with dead fetus; one was an abdominal pregnancy. The child was born alive, weighing 7½ pounds (3.4 Kg.), and when last heard from was in good condition. The mother died of general peritonitis on the sixteenth day. The third case was also an abdominal pregnancy with death of both the mother and the fetus. During twenty years, 367 patients with extra-uterine pregnancy were admitted to the Charity Hospital. All were negro women; four were primiparas and seven were multiparas.

Multiple Atresia of Ileum.—A case of multiple atresia of the ileum with complete separation of a segment of bowel is reported by Erb. The absence of bile pigment below the upper atresia would indicate that the occlusions had occurred before the third or fourth month of intra-uterine life. The presence of a peritoneal adhesion suggests that the cause of these atresias was an early intra-uterine peritonitis.

Effect of Thyroid Extract on Gastric Secretion.—Truesdell asserts that thyroid extract caused a decrease in body weight, increase in rate of pulse, slight increase in body temperature, increased restlessness and slight diarrhea. A decrease in continuous secretion of gastric juice was observed in all cases. The gastric secretion following a meal was decreased during thyroid feeding, the rate and extent of the effect depending on the amount of the thyroid fed and the individual resistance.

Effect of Hot Baths.—The results of experimental observations are summarized by Landis et al. as follows: Hot baths cause a hyperpnea whose severity depends on the rate of rise of body temperature and also on the temperature level at which the rise takes place. Hyperpnea involves a change in both rate and depth. There is never a shadow respiration, except in the first few moments when there is strong skin stimulation and during the recovery period. The p_H change of blood to the alkaline side is apparently determined by the hyperpnea but is not proportional to it. There may take place an excretion of urine that is more alkaline than the blood, probably with varying efficiency in different individuals. Oxygen does not relieve tetany, but carbon dioxide gives definite improvement. On two occasions a change in the p_H of the blood toward the acid side was demonstrable within a few minutes of the onset of definite tetany, and the p_H change was accompanied by a fall in the carbon dioxide content of the blood. This might readily be explained if lactic acid was produced during tetany. No evidence was obtained of any definite p_H level at which tetany would occur, nor even of any critical degree of change of the p_H level.

Regeneration of Pancreatic Tissue from Transplanted Pancreatic Duct.—Shaw and Latimer aver that in completely or partially pancreatectomized dogs (the diabetes being con trolled by insulin) homografts of the pancreatic duct in the intestinal wall become vascularized and undergo varying degrees of differentiation or regeneration toward pancreas tissue. In experiments prolonged for two months or more regeneration of ductlets was always in evidence, with some indications of acini and islet formation. When the transplanted and regenerating duct does not establish connection with the lumen of the gut, secretion accumulates in the ducts. This factor probably retards the regeneration of pancreas tissue.

Effect of Light on Blood Calcium.—Reed and Tweedy show that direct irradiation of blood in vivo with a carbon arc-light does not produce any immediate change in blood calcium in dogs under ether anesthesia.

Glucose Isomer in Blood.—According to Visscher, present evidence does not support the conception that the sugar in blood is the unstable gamma glucose.

Blood Counts in Vitamin A Deficiency Disease.—Falconer is of the opinion that changes in the relative number of platelets, red cells and white cells in the blood of rats are not striking enough, or constant enough, to constitute a specific lesion of vitamin A deficiency in these animals.

Suprarenal Transplantation.—Suprarenal transplantation was performed by Blodinger et al. in fifteen dogs. Fourteen were autotransplants; one was a homotransplant. The sites of grafting were the kidney, spleen, omentum and rectus muscle. Second operations, consisting in the removal of the nontransplanted gland, were done at intervals ranging from five to eighty days after the first operation. Following the second operation, death occurred in every case with symptoms of suprarenal insufficiency. In thirteen cases death resulted in less than twenty-four hours after operation, the average being eighteen hours. The remaining two animals lived ninety-four and ninety-five hours, respectively, after the second operation, succumbing with typical symptoms. In one animal a two stage double suprarenalectomy with no transplantation was done, the dog dying eight hours following removal of the second gland. The kidney seemed to be the best site for transplantation, the graft apparently being kept alive longer there than in other sites used. The grafts in muscle were most rapidly destroyed and absorbed.

Review of Urologic Surgery. A. J. Scholl and others, Los Angeles.—p. 928.

Endothelial Myeloma.—The fifty-four cases analyzed by Connor are considered important enough clinically and pathologically to report in full. The belief that these form an entity separable from osteogenic sarcoma is borne out by these characteristics: their almost constant location in the shafts of the long bones and in flat bones in which osteogenic sarcoma seldom occurs; their peculiar morphology, the type cell being easily distinguished from the osteoblast in most cases, and their susceptibility to radium and roentgen-ray treatment. The cells do not form an intercellular substance that will stain with the dyes used to differentiate collagen, bone and cartilage. At the same time, the cells are separable from those arising from the primitive hemocytoblast, and are considered, therefore, to be different from other various forms of myeloma which presumably arise from that cell. They resemble other myelomas by their predilection to metastasize to other bones. They occur in children mainly, and many of them are preceded by trauma and by signs of inflammation, apparently resulting from the trauma, this inflammatory reaction passing so imperceptibly into malignant disease that the two seem inextricably associated in the early stage. Histologically, they may be divided into angiomatous, reticular and diffuse tumors. Several important characteristics almost constantly associated with the tumor are the slow development with intermittent pain, swelling that may recede only to return and to become progressive, and the distressingly frequent confusion with chronic osteomyelitis clinically, roentgenologically and even, occasionally, histologically. As a final distinguishing point, the therapeutic radium or roentgen-ray test is advocated, this tumor, in contrast to osteogenic sarcoma, usually melting under the influence of these forces. Contrary to the opinion of Ewing and others, it is thought that endothelial myeloma arises as a solitary tumor, the multiple tumors appearing as actual metastases, and for this reason it is believed that amputation in the early stage is a form of treatment to be considered, though apparently radium has cured several cases. The prognosis, with a combination of surgery and irradiation, is not always death. Patients have lived for five years or longer, one sixteen years, after amputation, and many who have been treated by a combination of surgery, radium, roentgen-ray and sometimes Coley's toxins, are living over three years after the onset of the disease. The prognosis seems distinctly better than that of osteogenic sarcoma and other myelomas, and for this reason it is urged that these be considered special cases, in which, by energetic measures, a permanent cure may be possible.

Experimental Hydronephrosis.—This is the fourth paper in the series of reports made by Hinman and Hepler. The particular problem studied was the result of simultaneous ligation of the posterior branch of the renal artery and the ureter on the same side. The findings were: Because of the almost complete absence of arterial anastomosis, either intrarenal or extrarenal, ligation of the posterior branch of the renal artery causes infarction and throws out of function from one third to one half of the kidney. When this procedure is combined with total ureteral obstruction on the same side, there are produced in a remarkably short time enormous sacculations or diverticula of the infarcted area.

The effect is due to the lessened resistance of the degenerated parenchyma to urinary back pressure, and emphasizes, in an exaggerated manner, the significance of blood supply to hydronephrotic dilation. The absence of hydronephrosis in two specimens of this series, both of which showed a focal suppurative nephritis, confirms the belief in the importance of early infection with its resulting anuria in the production of primary atrophy when the ureter is completely obstructed.

Angio-Endothelioma of Bone.—Two cases are analyzed by Kolodny to show that angio-endothelioma of bone is a true pathologic entity, although it is exceedingly rare. He insists that, unless the diagnosis of endothelioma of bone is arrived at only after all the evidence is clear and conclusive, endotheliomas will continue to be the graveyard of those uncommon complex tumors of which the present day knowledge is extremely meager. Not by dodging and side-stepping the question of recognition of angio-endothelioma of the bone as an existing disease but by careful and intensive study of similar tumors and by elimination of all those which are of questionable origin will this be accomplished.

Bone Formation in Osteogenic Sarcoma.—The following hypothesis is put forward by Eising: Sarcoma in bone is a malignancy of the softer structures and connective tissues in bone, progressing in the matrix and along the pathway of the haversian canals and blood vessels. The new bone proliferation in osteogenic sarcoma is a secondary process and is the result of an attempt at the establishment of a natural barrier to the intrusion of the neoplastic process.

Interstitial Growth in Long Bones. — Haas asserts that interstitial proliferation of osseous tissue plays no part in the elongation of a growing bone, either in the mature bone or the young osteoid tissue on the epiphyseal cartilage plate. Length growth of bone is entirely dependent on the purposeful multiplication of the cartilage cells of the epiphyseal cartilage plate.

Strangulated Hernia and Viability of Intestine. — In two cases of strangulated hernia coming to operation, the contents of the sac were thought viable and were therefore replaced within the abdomen. Subsequent necropsies revealed gangrene of these intestinal loops with a plastic peritonitis. In order to determine the frequency of this untoward complication, Beller and Colp made a statistical review of 278 cases of strangulated hernia occurring among 4,139 cases of abdominal hernia, an incidence of 6.7 per cent. Apparently, the ability of nature to resurrect the viability of the average injured intestine has been exaggerated. In this series there were sixty-nine cases in which the compromised intestine had passed beyond the stage of congestion. Twenty-two of these were definitely gangrenous, and resection was performed. In forty-seven, after due deliberation, the contents were thought viable and were therefore reduced. Fourteen, or 30 per cent, of these patients subsequently died, the clinical picture many times resembling either intestinal obstruction, peritonitis or both. The authors assert that when viability of the intestine is questionable, resection need not be performed as a matter of routine because the involved bowel, adequately protected, may be left exposed in the wound for from six to eight hours before its fate is decided.

Does Artificial Pneumothorax Prevent Formation of Pleural Effusions?—From their experiments Carlson and Bunnell conclude that not enough pressure can be used in artificial pneumothorax either to prevent or to lessen the formation of pleural effusion, which so frequently jeopardizes results following thoracotomy. The old procedure of producing adhesions between the visceral and parietal pleura, which was long ago advocated by Sauerbruch and others, gives the better results. Aspiration of all the air following tight closure of the chest wall and early and repeated aspiration of any fluid formed is therefore indicated. The fixation of the visceral pleura to the thoracic wall by catgut sutures might assist in this process. Pneumothorax encourages the increase and spread of pleural infection. The danger from excess of pneumothorax in healthy normal persons with normal mediastinums is by no means a matter of minor importance.

Thyroid Tumors and Heart Disease.—Experience has convinced Arneill that great numbers of toxic adenomas go unrecognized and that as a result many patients die a cardiovascular death unnecessarily. Early recognition and operation would have cured these patients. Every examination of a patient should include a careful inspection and palpation of the neck. Whenever possible, this should be supplemented by a fluoroscopic examination of the chest in order to determine the presence or absence of substernal or intrathoracic goiter. If this plan is followed as a routine, innumerable cases of thyroid disease will be detected which would otherwise go unrecognized. In addition to these examinations, basal metabolic rates should be determined whenever possible.

Pathology of Chronic Encephalitis.—The pathologic findings in a fatal case of chronic epidemic encephalitis are given by Greig. The disease was myoclonic in type, with twitching, marked clonic movements, and a few generalized convulsions, epileptiform in nature. The disease terminated after a course of about nine months with symptoms of a marked myelitis. Although the case was chronic in type, the microscopic examination disclosed little thickening of the vessel walls as an indication of past perivascular infiltration. The changes found compare with those generally found. In addition, a number of less common changes were noted. Beginning in about the middle of the thoracic cord there was seen an increase in the lipochrome element of the nerve cells, and with gradually ascending levels this increase became more marked until in the nuclei opposite the fourth ventricle the change assumed the character of collections of golden brown pigment granules. Some of the cells were filled almost to engorgement, while others had only a few scattered granules. In some cells the granules seemed to be collected in the form of a shell about a central hyaline mass with the cell nucleus pushed to one side. Not all of the nuclei were involved. A group of affected cells would be surrounded by unaffected groups. This change was found up to the lenticular nucleus, in which there was a gradual shading off to the normal amount of the lipochrome element. In the cord throughout the posterior columns and the posterior portion of the lateral columns, beginning in the upper midthoracic region, and culminating in number and size in the lower cervical region, were found a large number of small, round, almost black homogeneous bodies, somewhat resembling corpora amylacea. The evidences of myelitis were noted as low as the midthoracic region.

Tubercle Vaccine Made from Wax-Free Cultures.—On agar medium made from bone instead of meat infusion, the tubercle bacillus grows wax free (i. e., nonacid proof) in the first generation. Whitman and Chambers found that vaccines prepared by the customary method from such wax-free cultures of an old, greatly attenuated strain of human type bacillus afford practically complete protection to guinea-pigs against subsequent injection of overwhelming doses of virulent bovine bacilli. This protection lasts for about one year, and no doubt for a longer time, though in somewhat lower titer. The same vaccine seems to have considerable curative value in established tuberculosis.

Phagocytic Cell in Bone Marrow in Pernicious Anemia.—The purpose of Doan's study was to determine the type of phagocytic cell that is found in increased numbers in the bone marrow in pernicious anemia In general, there is a reversal of the normal in the ratio of clasmatocytes in the spleen to clasmatocytes in the bone marrow in pernicious anemia, with a marked tendency toward the phagocytosis of young, immature, nucleated red blood cells in the bone marrow. The peripheral blood picture suggests that these cells had never been in circulation Doan's observations do not indicate that the spleen takes any directly active part in an increased destruction of blood in pernicious anemia.

Tumor Susceptibility and Heredity.—The facts presented by Lynch indicate that susceptibility to the development of tumors in the lung is an inherited character.

Immunity to Tetanus.—Additional data are presented by Tenbroeck and Bauer on the fact that carriers of tetanus spores are relatively immune to tetanus. They found that this immunity is specific for the serologic type of tetanus bacilli fed or injected, and that the antitoxin content of the serum does not indicate the degree of resistance to infection. As there is no relation between the amount of antitoxin in the blood and immunity to tetanus, the authors believe that other bodies, specific or type, must occur and make for the immunity observed.

Biology of Streptococcus.—Stevens and Dochez assert that erysipelas strains form a closely related group of hemolytic streptococci. Scarlatinal strains form an equally compact group The two groups are related to pyogenic strains, but less closely than the strains within the groups. These groups are related to pyogenic strains, but less closely than they are related to each other.

Compensatory Hypertrophy of Suprarenal Cortex.—The MacKays were able to determine that removal of one suprarenal is followed by hypertrophy of the remaining gland. The increase in size of the whole gland is due entirely to hypertrophy of the cortex and amounted to approximately 91 per cent and was due in large part, if not entirely, to an increase in the size of the cells. No increase in the size of the medulla or its cells was found.

Autoplastic Thymus Transplantations.—Gottesman and Jaffe found that thymus gland of young rats autotransplants easily when inserted into the muscles of the abdominal wall. The regeneration is usually complete by the fourteenth day, when the new formed thymic lobules show differentiation into cortical and medullary zones.

Bacteriology of Common Cold.—The normal bacterial flora of the nose and throat of thirteen individuals has been studied by Shibley, Hanger and Dochez over periods ranging from five to nine months. No bacteria were found in early cold cultures to which a causative rôle could be assigned. In the course of colds, the basic flora of the nose was often scanty in the early stages. The throat showed reduction of prominence or alterations in predominance of the basic flora. Certain organisms were prominent in colds, usually as late or secondary invaders; these included *Staphylococcus aureus*, hemolytic streptococci, and *B. influenzae*. There was a striking increase in the incidence of hemolytic streptococci in throat infections.

Wassermann Reaction in Experimental Syphilis.—Observations made by Herrold of the Wassermann reactions in experimental syphilis of rabbits indicate that the serologic response is not identical in every instance. There is also a vacillation in the reaction to some extent. "These results in rabbits suggest that if repeated Wassermann tests were made in cases of suspected latent syphilis, many patients might be found to be syphilitic whose syphilis is now overlooked.

Human Intestinal Carriers of Tetanus Spores.—Four hundred and eighty-seven specimens of human feces from California have been examined by Bauer and Meyer and 24.6 per cent were found positive for tetanus spores. Of the 120 tetanus bacilli isolated from these specimens, 63.3 per cent were type 1; 7.5 per cent, type 2; 17.5 per cent, type 3; 2.5 per cent, type 4, and 5 per cent, type 5. Type 6 had not been found. In addition to these, three strains of tetanus bacilli have been found which were not agglutinated with any of six type serums tested. Type 7 serum was not available; therefore it was not determined whether these strains are type 7 or belong to a new serologic group heretofore not described.

Döderlein's Vaginal Bacillus.—The vaginal flora of ninety-eight pregnant women was examined by Lash and Kaplan by means of smears and cultures. Döderlein's bacillus occurred in forty-one instances, while isolated in only thirteen instances. Failure to cultivate in a greater number of cases was probably due to more rapid growth of the associated organisms. The morphology, cultural characteristics, biochemical, pathogenic properties and immunologic reactions of four strains were studied; three could be classified under the general group of lactobacillus, while one resembled a diphtheroid. Serologically, they are distinct, but there may be some relationship. The name *Lactobacillus vaginae* is proposed as a provisional name for the Döderlein strain B.

Organism of Actinomyces-Like Tonsillar Granules.—From an actinomyces-like tonsillar granule, a weakly gram-positive flexible motile anaerobic organism has been isolated by Tunnicliff that produces in pure culture rosettes and test tube brush-like forms similar to those seen in the original material.

Fracture of Rami of Pubic Bones.—As the result of being crushed between two coal cars, Gardner's patient sustained a fracture of the rami of both pubic bones and some insignificant skin abrasions; nevertheless, he died from a gas bacillus (Welch) infection six days later. The man had been healthy previously, and the postmortem did not disclose any rupture of any part of the intestine, although the sigmoid and rectum were stained with subperitoneal hemorrhage. All other organs were unaffected. Evidently the gas bacillus infection was autogenous, gaining access to the pelvic tissue from the intestine, and thence entering the blood stream as a terminal event.

Tonsillomycoses.—Castellani reports four cases of tonsillomoniliasis; two cases of tonsillo-oidiosis; one case of tonsillowilliasis, and three cases of tonsillohemisforosis. He asserts that affections of the tonsils due to fungi higher than bacteria (mycetes) are not very rare. He has seen cases in tropical and subtropical countries and also in Europe and in England. They may be clinically separated into two groups: chronic tonsillomycoses and acute tonsillomycoses. Acute tonsillomycoses may at times clinically simulate diphtheria, Plaut-Vincent's angina and follicular tonsillitis. The treatment consists in local applications of glycerin of borax, and, most efficacious, a phenol or a chlorine spray.

Cholecystitis.—A study of 400 cases has convinced Judd that if a patient had a typical history of cholecystic disease, with characteristic colicky pain, he would be relieved of his symptoms if the gallbladder were removed, whether or not it showed recognizable disease. This study furthermore seemed to indicate that in cases of cholecystitis grade 1, in which the clinical manifestations were definite but disease unrecognizable at operation, cholecystectomy was followed by cure in a higher percentage than in the cases in which the disease of the gallbladder was graded 2, 3 or 4. The study furthermore showed that, if the patient's symptoms were of the chronic dyspeptic type or if the predominant features were soreness, tenderness, and aching in the side, the likelihood of cholecystectomy promoting cure was not great.

Cholecystitis and Diabetes.—Ricen has succeeded in demonstrating experimentally that lesions of the islands of Langerhans, resulting in diabetic symptoms, can be produced by hematogenous infections with *Streptococcus hemolyticus* and *B. typhosus,* if carried on for a sufficiently long period. He has never succeeded in lowering the sugar tolerance in animals with their gallbladders removed, which he thinks points to the importance of the infected gallbladder in injuring the pancreas, and particularly the islands of Langerhans, to such an extent as to produce diabetic symptoms. It is interesting to note that, whenever the injections produced febrile reaction, the micro-organisms injected were found in the gallbladder.

Experimental Visceral Hemorrhages.—Manville and his associates were able to produce experimentally in rats a hemorrhagic condition which seems to be analogous in many respects to that found in infants showing the hemorrhagic diathesis.

*Status of Ethylene as Anesthetic. C. L. Hewer.—p. 174.
Eliminating Static from Operating Rooms to Avoid Accidents with Anesthetics. E. K. McKesson.—p. 178.

Status of Ethylene as Anesthetic.—Hewer is of the opinion that ethylene must be given a definite place in anesthesia, and, in his opinion, it possesses advantages in certain cases which are not to be obtained by the employment of any other drug. The chief value of ethylene-oxygen anesthesia is for operations of medium severity lasting for a considerable time. In an average case, it permits of (*a*) a rapid and pleasant induction; (*b*) moderate relaxation without cyanosis, and (*c*) a quick recovery, with few, if any, after-effects. For short minor proceedings, ethylene offers no advantages over nitrous oxide and, indeed, is more likely to give rise to nausea or vomiting. At the other end of the scale, for extensive laparotomies, etc., in which absolute muscular relaxation and minimal respiratory movements are essential, ethylene cannot compare with the endotracheal nitrous oxide-oxygen-ether technic. A further use of ethylene-oxygen anesthesia is as an adjuvant to regional analgesia; e. g., in cases of gastrectomy performed under paravertebral or splanchnic block. It is undoubtedly preferable to pure nitrous oxide-oxygen in these combined methods, as respiration will be shallow and all cyanosis avoided without the disadvantage of any added ether.

Etiology of Accidental Hemorrhage and Placental Infarction.—The experiments reported on by Browne show that nephritis, acute or chronic, is an important predisposing factor in the production of accidental hemorrhage and placental infarction, and that toxemia is the exciting cause. It is believed that organisms only act by setting up an acute exacerbation of the nephritis, and that they do not lead directly to the hemorrhage, the latter being caused by endogenous poisons held up in the circulation by the acutely injured kidney.

Acute Suffocative Pulmonary Edema.—Merrin et al. report three cases of acute suffocative pulmonary edema in which treatment was with morphine. All three patients had no history of a previous attack, and all had valvular disease of the heart. Coleman has seen five cases that show that acute suffocative pulmonary edema occurs in a variety of chronic diseases—chronic regurgitation, asthma, and mediastinal neoplasm. Julian reports a case in which antimony tartrate acted very satisfactorily. In Spackman's case, bleeding gave speedy relief.

Changes in Vomiting of Pregnancy.—A study made by Drennan and Hicks of four cases of pernicious vomiting of pregnancy shows the importance of estimating the percentage of ammonia nitrogen excretion in the urine, and the necessity for repeated examinations of this "ammonia coefficient." In the toxic form, the ammonia excretion remains high, but may show marked fluctuations, even in spite of clinical improvement. The percentage of ammonia excretion—above the normal—gives little indication of the gravity of the case. One of the cases studied terminated in death, and a necropsy was performed. The injury, in the toxic cases, affects the liver particularly, but the kidney may also suffer. The nature of the liver injury is a toxic necrosis affecting especially the central area of the lobule. The cause of the injury appears to be derived from the fetal products, as removal of these leads to recovery and a return to normal of the ammonia excretion. There may, however, be prolonged after-effects of toxemia. Too long a delay in removing the products of conception may lead to irreparable damage. The neurotic type of case shows no increase in ammonia excretion, or only a transient rise, which may be due to other factors than toxic injury to the liver.

Influence of Exercise on Blood and Urine Phosphates.—It is shown by Havard and Reay that after short vigorous unaccustomed exercise the inorganic phosphate in blood first rises a little above, then falls considerably below, the normal value in men. It is thought probable that the changes observed in blood phosphate are due mainly to changes in the lactacidogen content of the muscles. The changes observed in the urine seem to be due mainly to the fleeting acidosis caused by the lactic acid formed.

Production of Pulmonary Edema.—Lambert and Gremels assert that the principal cause of pulmonary edema is the injury to the capillary endothelium, and the greater permeability thereby produced. There is a gradual steady increase in the flow through the coronary vessels in the course of experiment—which may amount to five times the original rate. Since changes in the intima of the cardiac vessels are observed, similar to those described in the lungs, the authors regard this increase as the response of the coronary vessels to the toxic effect exerted by the defibrinated blood. It is suggested that in certain cases of pulmonary edema as observed clinically, similar effects may take place through toxic action of the blood on the pulmonary vessels. This factor may enter into the causation of cardiac edema.

Crossed Dystopia of Kidney. A. J. Compton.—p. 810.
*Lesion of Pons Varolii Occurring Under General Anesthesia. W. J. McCardie and H. W. Featherstone.—p. 810.

Blood Sugar Studies in Epidemic Encephalitis.—McCowan and his associates found on study of cases that in lethargic postencephalitis there is definite derangement of carbohydrate metabolism, as shown by the blood sugar curves. The levulose test does not support the contention that there is definite permanent hepatic insufficiency in lethargic postencephalitis. The majority of lethargic postencephalitis cases show a hyperglycemia following glucose ingestion, markedly sustained in 50 per cent of cases. The mental states of depression and stupor were associated with the most pronounced abnormalities of carbohydrate metabolism. No correlation could be found between the clinical pictures and the types of blood sugar curves obtained. Although no diagnostic value can be placed on blood sugar curves in lethargic postencephalitis, the fact that the only normal curve was obtained in a patient who had recovered from his psychosis suggests that prognostic significance may be attached to them. The hyperglycemia found in all the cases is quite in keeping with the suggestion that lethargic encephalitis is of the nature of a toxemia, usually acute in onset, but becoming chronic in nature.

Steam Cautery.—In the destruction of malignant tumors, Souttar makes use of a slow penetration of heat from a cautery maintained at a low temperature, and this is very conveniently done by a current of dry steam. Souttar uses an instrument of his own device founded on this principle. The cautery is described fully.

Electrocardiograms in Rheumatic Carditis.—Fifty children with evidence of active rheumatic carditis have been examined electrocardiographically by Bain and Hamilton. Lengthening of the auriculoventricular conduction time was present in two cases. Impaired intraventricular conduction was present in one case. Abnormalities in the T wave in leads 2 and 3 occurred in five cases. Extra-auricular systoles occurred in one case. Preponderance of one ventricle over the other was unusual; a right-sided preponderance appeared to have a bad prognosis.

Lesion of Pons Occurring Under General Anesthesia.—One of the cases reported by McCardie and Featherstone was a thrombosis of the basilar arteries during an operation for advanced carcinoma of the breast. The case was one of acute dissemination of a very widely spread cancer. Such patients are toxic, and stop breathing very easily. It is believed possible that the slowing of the circulation from exhaustion led to the clotting of blood, which initiated the chain of events leading to the fatal issue. The second case was an unusual one—temporary recovery of respiration and heart beat in a patient who apparently had died under anesthesia, with a fatal sequel due to associated pontine injury. The heart beat was restored by cardiac massage. Respiration returned after apnea, which had persisted for seventy-five minutes. Stoppage of the circulation in the brain for ten minutes is accepted as the explanation of the fatal issue, which is so frequently the early sequel in cases of restoration of the heart beat by cardiac massage.

*Intussusception Case. D. S. Fairweather.—p. 863.
Skin Grafting in Acute Symblepharon. J. M. Ball.—p. 863.

Neoplasms of Testis.—Cairns reports on seventy-four patients treated by operation—fifty-five by orchidectomy and nineteen by the radical operation. All recovered from the operation and were discharged from the hospital. The rate of recovery is: after orchidectomy, 33.3 per cent, and after the radical operation, 31.2 per cent. These figures are not quite comparable for it so happens that relatively more spheroidal cell tumors were treated by orchidectomy, whereas in most of the cases in which the radical operation was done, the tumors were atypical teratomas and of greater malignancy. It follows that the radical operation was set a harder test than the local operation. On the whole, therefore, Cairns is of the opinion that the results are slightly in favor of the radical operation.

Serum Treatment of Diphtheria.—MacIntyre urges early diagnosis and routine injection in all suspicious cases with antitoxin at the first visit. For the type of case that is virulent from the onset he recommends the administration of large doses of serum partly by intravenous and partly by intramuscular injection.

Method of Cancer Research.—Gilford describes a deductive method of cancer research, a so-called Cartesian method advocated by Descartes some 300 years ago. As applied to the present problem it is based on the proposition that cancer of man is essentially an intrinsic disease, a piece of the man himself, and that for its solution all the data required are at hand. According to this view, the genesis of cancer is an affair of human genetics.

Radium Therapy of Tuberculous Adenitis.—Of fifty cases of tuberculous adenitis treated by Gosse with radium, thirty-seven patients are cured; nine, improved; three, not improved, and one, dead. The glands to be treated, having been carefully located and palpated, are marked out on the overlying skin with a dermographic pencil. Over these localities "half-strength" plates, i. e., plates covered by 2.5 mg. radium element to each square centimeter surface and covered by a sheet of Monel metal 0.3 mm. in thickness, are applied and held in place by pieces of adhesive plaster.

Intussusception.—The unusual features in Fairweather's case are: (1) the age of the patient, 14 years; (2) the alleged absence of blood in the feces; (3) the site of the intussusception, 18 inches (46 cm.) of the ileum; (4) the almost uneventful recovery after such an extensive resection and on a patient who had suffered five days before operation.

Fulminating Purpura.—Bullmore and his associates are convinced that in the case they report, there can be no doubt that the condition was due to hemolysis and that the organism was recovered from the blood both before and after death. The history of the illness would indicate that the malaise and headache were the symptoms of the onset of the toxemia, which terminated as a septicemia, the outstanding features being a fulminating purpura. It is surmised that the portal of entry was the tonsils.

Coagulation of Yolk by Bacterial Diastase E Lagrange —p 242

Production of Toxin by Tissue Freezing—In Speransky's experiments, a circumscribed portion of the brain cortex in dogs was treated with liquid carbon dioxide through the intact dura This induced an acute toxic encephalitis, with convulsions similar to epileptic seizures in man The carbon dioxide was applied to various occipital and parietal parts of the brain cortex except the motor centers, the phenomena were always the same There were no convulsions if the frozen area of the cortex was removed immediately Its removal after appearance of tonic convulsions did not arrest them The frozen part of the cortex from dogs in an epileptic condition was implanted beneath the dura mater (beyond the motor zone) in two healthy dogs They developed phenomena of epilepsy There seems to be a substance produced in the frozen nerve tissue which has a toxic action on the nervous system—a neurotoxin or rather an autoneurotoxin Immunization against the autotoxin was realized by repeated, gradually increased applications of the carbon dioxide, immunity was manifest in 15 per cent of the dogs surviving after an otherwise lethal application of the freezing procedure Immunity was induced also with implants of the frozen brain tissue Research is now under way on the prophylactic and therapeutic action of serums from immunized animals on different nervous manifestations in dogs The freezing procedure was applied to the thyroid, testicle or salivary gland, and changes appeared in the symmetrical organ, suggesting the action of a specific toxin It is possible that a toxin from freezing of cancer tissue might reduce the malignancy of the tumor, thus indirectly reenforcing the defensive forces

Scientific Mission Across the Sahara Desert P Durand —p 469

"Convalescents' Serum" from Animals in Prophylaxis of Typhus—Nicolle and Conseil report that experimental typhus in the ass resembles that in the guinea-pig but the blood of the ass is less virulent during the febrile stage In both these animals, however, the proteus bacteriologic test is negative but each produces an abundance of antibodies It might be possible to enhance the antibody production in the ass serum by reducing the animal's resisting powers (venesection superposed mild infection, or the like), repeating the inoculation did not seem to answer the purpose Certain antimicrobic serums seem to owe their action to the infection induced by the primary inoculation, and not to repetition of the inoculations The ass serum, in this case, is equivalent to a convalescent's serum, and they advocate its use in place of human convalescent serum in preventive work They suggest that this principle of utilizing the serum of cured asses might be applied in prevention of measles

The Influencing of One Microbian Race or Species by Another—Burnet's research was mainly with the paramelitensis and the way it influenced other microbes cultivated with it Both the antigen properties and the agglutinability could thus be transformed by the interaction not only of bacteria of the same types but of different species The modifications recall the phenomena of transmissible lysis, and the way in which bacteria resistant to the bacteriophage become modified in shape and antigen properties by its action His research further sustains the idea of the variability of microbian types and of cells in general, the complexity of species and gradation of varieties from the standpoint of a given characteristic also the heterogeneity of microbian cultures, and the orientation of the variations, which seem to occur always in a natural definite sense and to be irreversible

Cholesteremia in Children—The cholesterol content of the blood was determined by Baranski in ninety-five children of different ages Variations of the cholesterol in healthy infants appeared the same as in healthy adults Tuberculosis or other infectious diseases induced in children the same changes of cholesterol content in the blood as in adults In syphilitic children the *cholesterol* was lower than in syphilitic adults The cholesteremia was abnormally low in children with dystrophic disturbances, also in acute alimentary toxicoses It rose gradually as improvement progressed

Vaccine Treatment of Typhoid in Children—Spyropoulos applied intravenous injections of antityphoid vaccine in treatment of fifty children, aged from 2 to 15 In thirty-two cases a single injection brought about the gradual subsidence of fever and remarkable improvement, without any by-effects.

Convalescence was rapid in all. In four cases a second injection was given after two or four days. In two instances no effect was apparent. The results seemed to be better with an autogenous vaccine.

Genito-Abdominal Tuberculosis in Women. E. Toneff.—p. 205.

Intra-Uterine Transplantation of Ovary.—Serdukoff transplanted an ovary into the uterus in two sterile women at a laparotomy for salpingitis. Contrary to American and French operators, the ovary was implanted, not in the posterior wall of the uterus, but in the horn, on account of the intense vascularization in this region. He emphasizes that the abdominal surface of the ovary transplant should not be covered by peritoneum, since this may interfere with the regular rhythm of ovulation. Conservation of at least one ligament of the ovary, with intact vessels, is another important condition. The two women were reexamined six months later. All pains had disappeared completely, and menstruation was normal. The future will show if the results are complete, namely, if conception occurs.

Origin of Increase of Metabolism in Pregnancy.—Garipuy, Lassalle and Sendrail found clinical signs of exaggerated thyroid functioning only in one of sixteen pregnant women. They conclude that the higher basal metabolism in pregnancy is not connected with any thyroid reaction. Products eliminated by the fetus and placenta seem to stimulate the metabolism in the maternal organism, thus acting like hormones.

Transient Weakening of the Heart in Tuberculosis. Dumas and Mollard.—p. 675.
*Multiple Anaphylaxis. L. Duvernay.—p. 678.

Multiple Anaphylaxis.—*Duvernay's patient presented anaphylaxis* which at first had been specific for milk and cows, but later the manifestations appeared from any toxic influence, sore throat, intestinal derangement, vaccine, strawberries or mosquito bite. The attacks were evidently of the colloidoclasis type, with vasodilatation, periods of pulmonary edema, asthma, urticaria, Quincke's edema and similar manifestations in joints—an actual acute articular rheumatism, the joints swelling and painful within an hour, the condition returning to normal in three hours. The only symptoms lacking from the clinical picture of anaphylaxis were migraine and eczema. The case further demonstrates the inhibiting action of an emotional shock, also of pregnancy, and especially of colchicin. Colchicin pills arrested the urticaria or reduced it, and Duvernay queries whether its efficacy in gout may not be explained by the assumption of an anaphylactic element in gout.

*Syphilis in the Third Generation. G. Cornaz.—p. 220.
The Bex-les-Bains Mineral Waters. R. F. Chollet.—p. 228.

Cystic Neuroglioma of the Cerebellum.—Perret treated a man, aged 32, with the diagnosis of a cystic tumor, probably located in the right cranial fossa. At that time the patient was blind and in a comatose condition. The skull was punctured at that point, and 20 cc. of a limpid fluid was released. This was followed by immediate relief, and rapid disappearance of all the symptoms. A week later the patient was able to walk and write letters. In six weeks the condition grew suddenly worse. The puncture was repeated and followed by trephining and draining. He recovered and went back to his regular occupation. The recovery persisted for three years. Then a recurrence required a second trephining, with restoration to health for two years. A second recurrence did not yield to any measures, and the patient died in coma. At necropsy the tumor appeared to be a neuroglioma with cystic degeneration. A fall on the back of the head at the age of 7, which had induced two epileptiform seizures in childhood, and severe headache at puberty, may have caused formation of a neuroglioma after a long period of incubation.

Syphilis of the Third Generation.—The history of Cornaz' patient is as follows: Her father had contracted syphilis eighteen months before she was born. Twice she was treated for keratitis and now presents corneal opacities, with evidences of dystrophic disturbance in bone and teeth from unmistakable congenital syphilis. Married at 29, she gave birth to two apparently healthy children within six years. Then came a third infant, stillborn. Necropsy disclosed congenital syphilis with spirochetes in the organs. Syphilis, Cornaz says, was positively excluded in the husband. The case shows how ineffectual is local treatment in congenital syphilis. Only intensive and prolonged general therapy should be employed, even if the Wassermann test is negative.

Dental Prosthesis in Digestion Disturbances. C. D'Alise.—p. 324.
Malignant Tertian Malaria. A. Tarsitano.—p. 328.

Contralateral Warning Zone in Pneumothorax. — Campani and Fiori confirm the frequency of Campani's contralateral warning sign in artificial pneumothorax with adhesions, kept at high pressure. It consists in a pleuropulmonary congestion localized in the fifth to the seventh interspace in the axillary line. It indicates the danger of pleurisy on the pneumothorax side. The symptom is usually transitory, unless the insufflations are pushed. It is more frequent on the left side. They are inclined to explain it by some mechanical indirect compression rather than by a sympathetic reflex.

Rivista di Clinica Pediatrica, Florence

24: 145-216 (March 22) 1926

*Celiac Disease of Pancreatic Origin. L. Magni and E. Pirami.—p. 145.
Herpes Zoster and Chickenpox. F. Lo Presti-Seminerio.—p. 165.

Pathogenesis of Spasmophilia. E. De Micheli.—p. 184.

Celiac Disease of Pancreatic Origin.—Magni and Pirami report a case of intestinal infantilism. The chronic diarrhea, with steatorrhea, was quite pronounced. They attribute the disease to a disturbance of the pancreas.

24: 217-288 (April 10) 1926

*Tuberculous Orchiepididymitis. F. Allodi.—p. 217.
The Kottmann Test. D. Bottacin.—p. 227.
The Benzoin Test. P. Dotti.—p. 236.
*Liver Lesions and Tetany. D. Larini.—p. 249.

Tuberculous Orchiepididymitis.—Allodi deplores the somatic and mental sequels of surgical treatment of tuberculous orchiepididymitis, especially in children. Besides this, it seems to induce generalization of the disease. He gives every other day, or twice a week, subcutaneous iodine injections, with a rest for ten days after each two months of treatment. The formula is 1 Gm. of iodine; 2 Gm. of potassium iodide, and 100 Gm. of distilled water: Inject 1 cc. He reports good results in seven children from 2½ to 4 years of age.

Liver Lesions and Tetany.—Larini reports two cases of tetany in children with grave fatty degeneration of the liver, revealed by necropsy. He regards these lesions as the cause of the syndrome.

Laparotomy for Bladder Stone on Hairpin. Ahumada.—p. 588.
Bougie Perforates Uterus and Migrates to the Spleen. F. F. Carranza and H. R. Martinez Leanes.—p. 590.
*Serologic Test for Cancer. N. Capizzano.—p. 597.

The Roffo Stain Test for Cancer.—Capizzano has confirmed in the field of gynecology Roffo's statements in regard to the differential importance of the color reaction when five drops of a 0.03 per cent solution of neutral red are added to 2 cc. of blood serum. In twenty-five women, normal or with nonmalignant affections, or pregnant women, the tint of the fluid was constantly yellow. In twenty-four cases of cancer of the cervix or body of the uterus, the tint of the fluid changed to pink in 70 per cent. In the discussion that followed, Carranza stated that he had found the reaction positive in a case of a precancer leukoplakia of the uterus, and others confirmed that a previously positive reaction became negative in two months after removal of the cancer. Roffo has found that profusely secreting malignant tumors yield a larger percentage of positive reactions. With skin cancer, the proportion of positive responses was not over 30 per cent.

Priority in Differentiation of Paratyphoid Fever. — Rivas Morales relates that Jan. 2, 1896, Mosquera and Risquez called the attention of the local medical society at Caracas to series of cases of an anomalous typhoid fever, a pseudotyphoid. They ascribed it to a virulent type of colon bacillus. Their report was published four months later in the organ of the society, and the data were examined by Gilbert at Paris and by Penny and Kinyoun at Washington. In November, 1896, Achard and Bensaude, Paris, called attention likewise to infections which they designated as paratyphoid, with bacilli intermediate between typhoid and colon bacilli. Their bibliography (1904) contained *no mention* of Mosquera or Risquez. Risquez adds that the alleged myth of "typhomalaria" was placed on a solid footing by his discovery of bacilli of the typhoid group and malaria parasites in the same microscopic field.

Relations Between Development of the Brain and of the Suprarenals. J. Moreira da Fonseca.—p. 15.

The Kahn Serologic Test in Syphilis. — Magalhães and Crespo de Castro report new series of tests which confirm the findings of their previous series. In their 180 subjects, there were 21 in the primary stage of syphilis, 25 in the second and 19 in the third stage, with 51 in a latent phase, 31 with congenital syphilis, and 43 with a negative Wassermann reaction. All were tested with both the Wassermann and the Kahn technics, and the findings harmonized in 97.8 per cent. The discordance of 2.2 per cent was in favor of the Kahn test as being more sensitive. In only 0.5 per cent was the Wassermann positive with a negative Kahn. The intensity of the reactions coincided in 84.4 per cent; the Kahn findings were more pronounced in 15.6 per cent.

Revista de Cirugía, Buenos Aires

Metal Bolts, Screws and Wire in Reconstruction of Bone After Fractures, and Remote Results.—Valls' roentgenograms sustain his assertion that the ultimate outcome could not be better than was actually realized in the nineteen patients recently reexamined from one to eleven years after the "metallic osteosynthesis." There had been no disturbances or by-effects from the metal implant in any instance. No special tolerance for either brass or steel was noted; both healed in place equally well. He has seen screws that had been removed from the greater trochanter after several years, and none of them had lost in weight; the screw had to be unscrewed to extract it.

Disarticulation of the Hip Joint.—Perpiñá and Sarasola claim superiority for their technic as it provides a fine stump while the incision avoids the large blood vessels, and they are easily ligated later. The limb in extension and slight abduction, the incision is carried at one stroke down through the capsule of the joint, the line running from 2 cm. below and inside the middle point of the inguinal groove to the tuberosity of the ischium. The only vessels severed are small ones. Then the head of the femur is twisted out of its socket, tearing the ligament. Rotating the thigh outward, increasing abduction, brings the femoral vessels into greater prominence, and a double ligature is applied. They prefer to ligate below the origin of the deep femoral, respecting the external circumflex. The almost right-angled cicatrix parallels the inguinal groove and extends on the thigh, not reaching the base of the stump. Six illustrations.

Treatment of Syphilis in Pregnancy. E. Klaften.—p. 371.

Blood Sugar in Mother and Fetus.—Hellmuth prefers the Folin-Wu method and sodium fluoride, which prevents glycolysis. The blood sugar is normal in pregnancy, and frequently becomes lower in the last two months. In eighteen of twenty-five labor cases, the blood sugar rose considerably (up to 228 mg. per hundred cubic centimeters). The blood sugar in the new-born child is always lower than in the mother, but it changes parallel with it.

Glycogen in Fetal Vagina.—Gragert found a large amount of glycogen in the squamous cells of the vagina in a fetus 16 cm. long.

Virulence of Vaginal Germs.—Louros explains the "blood virulence" of germs as detected by the Ruge-Philipp tests as only the maximum of virulence. His method (resistance to a 0.5 per cent solution of methylene blue) allows registration of lower grades of virulence—such as are sufficient for infection of the tissues, including the *peritoneum*. When he smeared such cultures on pieces of placenta, uterus, fat and peritoneum, and incubated, the germs grew into the tissue. Germs which were not resistant against methylene blue, remained on the surface. Avirulent germs produce much more acid from dextrose than the resistant and virulent strains. Therefore, the acidity of the vagina depends on the virulence of the germs. Hemolytic properties disappear in acid mediums. Virulent hemolytic germs do not produce enough acid, and therefore remain hemolytic. Avirulent hemolytic germs become anhemolytic. Virulent and resistant germs require higher temperatures for disinfection, and take stains only slowly.

Treatment of Syphilis in Pregnancy.—Kraul and Bodnar demonstrated the presence of arsenic and bismuth in the organs (including the brain), blood and amniotic fluid of fetuses whose *mothers had been receiving antisyphilitic treatment*. The placenta takes an active part in the transmission of the drugs. No stage of a pregnancy is too far advanced for the treatment, but if it is started early, hardly any of the children show signs of syphilis.

Rectal Cancer and Pregnancy.—Katz and Kaspar find a carcinoma of the rectum as a not entirely rare complication of pregnancy. In some cases, the development of the cancer seems to be in connection with the pregnancy, and there is recurrence of the tumor in the next pregnancy. This applies *especially to women with a cancer heredity and with polyps of the rectum*. The prognosis is comparatively good. It would be still better if the complaints of pregnant women as to rectal disturbances were always answered by examination of the rectum.

Central Action of Cocain and Its Substitutes. Offermann.—p. 600.
Rotation of Body Around Longitudinal Axis in Cerebellar Disease. J. Gerstmann.—p 635.

Motor Function, Body Build and Mental Characteristics.—Gurewitsch lists five different types of constitutional substandard motor functioning. They are usually accompanied by backward mental development, but not always. There seems, however, to be a connection between the motor function, the build and the mental condition. His research supplies the gap in the Kretschmer schizoid-pyknic-asthenic-athletic classification. The correlation between the constitutional build and the mental faculties is still more manifest when the motor functioning is included in the chain. There is a close connection between the handwriting and the constitution.

The Recent Religious Epidemic in Russia.—Goldbladt discusses the psychic epidemic which developed in Ukraine and spread over a large part of Russia in 1920-1923. This religious epidemic was based on the renovation of old religious paint*ings in churches and homes*. They lost their aspect of age and shone clean and bright as new. The miracle in a village home attracted crowds of 50,000 people and imposing religious services were held. He thinks the foundation for the superstition of the miracles was the cleansing and brightening effect of certain unusual atmospheric conditions *on the cupola* of the large church at Kiev. The people got the idea that religious objects were being miraculously renovated, and the mass suggestion spread so they imagined the old pictures looked as if they were rejuvenated. Here and there some ikon was surreptitiously cleaned, but as a rule the whole was based on autosuggestion, with visions and blurring of consciousness; there were no hysteric motor phenomena. The "ikon renovation" epidemic was distinguished more by its wide spread than by the intensity of the pathologic psychic picture. Six of twelve persons examined, presenting extreme cases of the delusion, were mentally substandard, hysterical women and girls The larger the number of persons involved in such a religious epidemic, the greater the tendency for the mentally healthy to be drawn into the circle He lays special stress on the numerous instances in which the people longed and prayed for the miracle to happen in their village or home, and their concentrated yearnings finally brought the miracle to pass before their eyes under the influence of religious faith, superstition privations, and the emotional strain of the war and the famine, etc

Waxy Degeneration of Muscles with Granuloma in Bone Marrow R Schmidt —p 378

Extirpation of the Roadway in the Stomach—Bauer's illustrations show the arrangement of the folds in the stomach which form a lengthwise track or roadway along which the food slides and which seems to be the exclusive site for round ulcer formation Ulcers elsewhere were of other nature in his experience This lengthwise tract seems to differ histologically from the rest of the stomach He presents data to prove that it is a rudimentary survival the natural continuation of the esophagus deep into the stomach The circulation corresponds to that of the esophagus, and defects do not heal here as elsewhere in the stomach He has been experimenting on dogs with extirpation of this strip down through the stomach and has applied the procedure in one clinical case with apparently complete recovery He reiterates in conclusion that whatever the primary factors may be, round gastric ulcer develops almost invariably in this tract, the *Magenstrasse*

Transplantation After Blocking the Defensive Forces—Lehmann and Tammann use the term *Vitalspeicherung* to express subcutaneous injection of a dye (trypan blue) to block the reticulo endothelial system When this was done preliminary to transplantation of a skin flap from another animal of the same species (mouse), the transplant healed in place, while this never occurred without the preliminary vital storage treatment Twenty-six colored plates show the details of the research, the findings sustaining, they say, the assumption that the blocking of the reticulo endothelial system prevents the natural reaction to cast off the foreign body The organism accepts it passively, as it were, and proceeds to supply it with blood, etc, as if it were part of the original organism This theory was confirmed by the successful healing of a second flap after blocking the reticulo endothelial apparatus when a previous transplant, while this apparatus was functioning normally, had been speedily cast off

Autohemotherapy T Hirsch —p 551

Vulvovaginitis in Children—Vogt points out that the urethra, cervix and rectum are much more frequently affected in the vulvovaginitis of little girls than has hitherto been assumed The long duration of the disease is explained by this The spreading of gonococci upward through the uterus and tubes is not infrequent This occurs sometimes at the onset of menstruation, after a long period of quiet Potentia coeundi might suffer by concretion of the labia and stenosis of the vagina Sterility is quite frequent

Treatment of Partial Deafness—Wodak has been trying large doses of arsenic in 100 patients suffering from otosclerosis and other affections impairing the hearing more or less He gave daily two pills, each containing 5 mg of sodium arsenate, and in grave cases, three or four pills The total amount given was about 300 mg An interval of three or four months followed He had fair results in two-thirds of his otosclerosis patients and in a similar proportion of other diseases

Møllgaard's Serum—Opitz and Kotzulla found no experimental evidence of antitoxic properties of Møllgaard's serum Its action did not differ from that of normal beef serum They claim that this control was omitted by Møllgaard

Facial Paralysis in Otitis—Manasse does not consider a facial paralysis occurring in the course of acute inflammation of the middle ear as indication for trephining

Prognosis of Scrofula—Connerth's statistics indicate that only a comparatively small percentage of those who have had scrofula are later affected by grave pulmonary tuberculosis

*Meningeal Affections J Schlesinger —p 631
*Treatment of Lancinating Pains O Stein —p 631

"Organic" Iron Preparations—Heubner finds that it is immaterial what admixture is added to the iron oxide in its use as an 'organic' preparation of iron The saccharate is cheap and makes combinations with proteins superfluous The question of bivalent or trivalent iron is more important The resorption of the former is better than of the colloidal preparations

The Cortex Coefficient—Economo estimates the number of cells in the human cerebral cortex at 14 billions Eight billions of them are large cells and six, smaller ones. The total weight of these cells is only about 21.5 Gm. and their volume 20.78 cc. The weight of the cortex is 581.3 Gm., the volume, 560 cc. The rest of the cortex consists of the gray matter. The ratio of the weight of the gray matter to the weight of the cells in man is 26. He believes that it is a good index of the organization of the cortex. Lower animals have a lower index (larger proportion of cells).

Psychiatry and Habitus.—Kolle is quite skeptical with regard to Kretschmer's somatic types. The pyknic habitus in cyclic psychoses is due chiefly to the fact that about four fifths of these patients are older, and the habitus simply corresponds to the age. Subjective ratings play an enormous rôle. Two investigators taught in the same school find a divergent percentage of types in a material of the same origin.

Serology of a Pneumococcus.—Berger and Engelmann changed a pneumococcus of group III into a strain of group II.

Peptidases in Fever.—Pfeiffer and Standenath test the degree of splitting of glycyltryptophan by the serum. A fever puncture in a rabbit did not increase the titer. Administration of tetrahydro-beta-naphthylamine and injections of a typhoid vaccine killed by heat gave also negative results. Addition of phenol as well as destruction of the cells caused by other means—such as vaccinia and colon infections—increased the titer.

Meningeal Affections.—Schlesinger observed, as one of the first signs of meningitis in infants and small children, a dissociation between the movements of the head and of the eyes. The children turn the head first, and the eyes follow only slowly.

Treatment of Lancinating Pains.—Stein had success in twenty-eight of thirty-two cases of lancinating pains in tabes with intravenous injections of 10 cc. of a 40 per cent solution of methenamine. Irritation of the bladder was noted in some of the patients thus treated. It disappeared after administration of 1 mg. of atropine sulphate.

Paralysis of the Intestine Treated with Injections in the Celiac Ganglion.—Rosenstein obtained movements of the intestines in cases of complete paralysis of the bowel (from peritonitis) by injecting 3 mg. of nicotine, in 30 cc. of water, around the celiac ganglion. He used Kappis' paravertebral technic. The injection does not necessarily cure the patient, who may die from sepsis. Köhler reports on experiments on animals. Nicotine was the only drug which proved effectual and harmless.

Endocarditis Lenta.—Heilborn finds that splenectomy may help in cases of recurring ulcerative endocarditis, if the clinical symptoms point to a marked participation of the spleen.

Slight Stomach Disturbances.—Weitz and Vollers found more pronounced disturbance of the gastric motor function than of the secretion of the stomach in indigestion.

Bronchial Asthma.—Van Leeuwen divides asthma-inducing substances into two groups: the A allergens contained in the air, and the B, the others, occurring in houses. He had excellent results when keeping the patients of the group B *at least over night in small chambers with sterilized mat*tresses, and the air supplied through a tube ending about 10 meters above the roof of the building. With the A type of asthma, he chills the air. The condensed vapor contains most of the A allergens. After this, he heats the air and supplies it to the patients.

Diagnostic Culture in Tuberculosis.—Hohn concludes that the problem of the diagnostic cultivation of tubercle bacilli is solved by the Löwenstein-Sumiyoshi method.

Wiener klinische Wochenschrift, Vienna

39: 377-408 (April 1) 1926

Lupus Erythematodes. S. Ehrmann. Supplement.—p. 1-24.

Chagas' Disease and Goiter.—Kraus finds that it has not been proven that the South American trypanosomiasis causes the goiter and myxedema. There are many regions in South America with endemic goiter (75 per cent; 30 per cent are cretins), and although the triatomas found there contain trypanosomas, no Chagas' disease is observed there.

Drugs with Hidden Iodine.—Kofler found iodine in several *preparations* sold as "pure nonpoisonous vegetable compounds."

Blunders and Dangers in Surgery—Hesse introduces a new department of the *Zentralblatt*—devoted to surgical blunders and dangers The department will accept even anonymous communications, which will be edited by specialists

Blunders in Surgery of Hernias—Stich reports a few instances of blunders made in surgical treatment of hernias In one instance, a piece of the colon wall, 10-12 cm long was resected in a case of sliding hernia—having been included in the ligature thrown around the hernial sac—and, what is perhaps still worse, the physician had not inspected the resected portion The patient died from peritonitis Retroperitoneal reposition of the hernial contents can be avoided if the surgeon does not omit the correct forceps fixation of the posterior wall of the hernial sac, even if he thinks that he knows all about surgery of hernias The bladder may be injured, especially if the surgeon tries to make a deep suture

Blunders in Surgery.—Perthes recalls a case of fracture of the femur below the trochanter which had healed in a right angle with a resulting grave shortening He intended to make a wedge-shaped osteotomy The bone was so hard that chiseling was impossible He used the case to demonstrate the advantage of a new method (boring holes) before another distinguished surgeon who was visiting him The result was a pseudarthrosis, because the sclerotic bone was unable to produce another callus The correct method would have been to operate distad from the fracture in the healthy bone He believes that the presence of the visitor influenced him unfavorably Thiersch declared once that a good orator must feel a sovereign contempt for his public This applies also to a good surgeon

Rectal Versus Vaginal Examination—Baum investigated in 864 obstetric cases the questions, how often an interna examination is necessary and how often the rectal examination furnishes satisfactory information Internal examinatio was comparatively rarely needed—only in about 8 per cen of the cases In this group, rectal examination failed in 8 per cent—especially with placenta praevia and prolapse o the umbilical cord

Chlorosis and Anemia of Pregnancy.—Esch reports case of low color index and erythrocyte count occurring in pregnancy They differ from pernicious anemia of pregnancy

Retroflexion and Accident—Futh regards Raaflaub's sig of recent traumatic retroflexion of the uterus as valuable Both inguinal regions are tender spontaneously as well a on pressure

Sign of Probable Pregnancy.—Gauss published in 1920 modification of Hegar s sign The cervix presents in th early *months* of pregnancy an abnormal motility It may b easily pushed to either side without entailing a corresponding *movement* of the uterus He found the sign in 146 of 14 pregnancies (including one in the first and fifty-five in th second month). The two failures (both in the second month) were corrected ten days later. The phenomenon is comparatively rare outside of pregnancy.

Factors in the Bearing Down Efforts of the Parturient.—Hoehne concludes that the lengthwise stretching of the lower segment of the uterus and of the round and uterosacral ligaments provokes the reflex pressing by the woman in labor. It may be produced experimentally in the later stages of labor by pressure on the perineum by fingers introduced into the vagina, and in earlier stages by lifting up the uterus with both hands. Premature bearing down efforts may cause rupture of the cervix. They should be avoided before the os is completely dilated. Any premature pressing indicates some anomaly in the labor.

Pfannenstiel's Transverse Incision.—Sarwey concludes that Pfannenstiel's transverse incision of the aponeurosis has every advantage over longitudinal incisions in all obstetric and gynecologic laparotomies.

**Theobromin and Test Diuresis. S. Litzner.—p. 313.*

Theobromine and Test Diuresis.—Litzner finds that theobromine sodium salicylate does not inhibit the water test diuresis. If a diuresis test is repeated on two consecutive days, the diuresis is always less on the second—whether the drug is administered or not. If the subject drinks plenty of water and eats salt on the first day, the diuresis is good on the second day.

*Paravertebral Anesthesia. H. Havlicek.—p. 368.

Duodenal Treatment of Cholecystitis.—Allard advises surgical intervention in cholecystitis, gallstones, or occlusion of the common bile duct, only when duodenal treatment fails. He injects in the evening pituitary extract intramuscularly (to empty the gallbladder), and gives afterward 1 mg. of atropine with some cholagogue. On the next day, he introduces the duodenal tube, and provokes the reflex again. He follows this with injection of 100-300 cc. of a 15 per cent solution of magnesium sulphate. Profuse diarrhea follows, but some of the gallstones may appear in the stool after the second day. The injection brings on a colic which he mitigates by papaverine, atropine or scopolamine. He repeats the treatment every fourth to eighth day. He never witnessed any bad effects in his 200 cases thus treated in the last two and a half years. It is hardly necessary, he adds, to emphasize that empyema of the gallbladder is a contra-indication to this treatment.

Injection of Caffeine Into the Cisterna.—Kulenkampff made an Alexander-Adams operation under local anesthesia in a young woman. Thirty-six hours later she stopped breathing. Lobelia and artificial respiration did not seem to help much. An injection of 0.08 cc. of caffeine into the cisterna resuscitated her.

Blood Chemistry in Blood Diseases.—Becher found in pernicious anemia large amounts of phenol and of indican in the blood. Even free phenol may occur. The aminonitrogen is increased—because of the increase in erythrocytes—in polycythemia. The combined and free aminonitrogen is much increased in leukemia. It is localized in the leukocytes.

Paravertebral Anesthesia.—Havlicek describes the technic of paravertebral injections.

Production of Tumor Resistance by Fatty Acids.—Nakahara's research was summarized in 1925 when published elsewhere (May 16, p. 1526).

Artificial Tumor from Injection of Pityrol.—Metastatic nodules were found in the lungs, kidney and spleen of the same structure as the primary fibromyxo-adenoma which had developed in the mammary gland of one of twelve rabbits injected subcutaneously with pityrol in olive oil, once or twice a month, for fifteen months.

Tumors in Fish.—Takahashi has collected 140 tumors in fishes, including practically all kinds of growths except myomas. Only one instance of a neuroma was found. Tumors containing guanin crystals—his "guanophoromas"—have never been found in warm-blooded animals. Sagawa describes a case of multiple fibromas on the skin of a gold fish, epitheliomas on others, and osteomas in other fishes. None of them seemed to be of parasitic origin.

The Endocrines with Rat Cancers.—Toriumi relates that all the endocrine glands and gonads showed retrogressive changes, but nothing specific for malignant disease.

Roentgen-Ray Diagnosis of Echinococcosis. A. Uspensky.—p. 244.

Pathogenesis of Septic Endocarditis.—Egoroff induced hemorrhagic infarction in the aortic valves of a sheep by injecting crushed blood clots into the jugular vein. It shows, he says, that there were capillaries in the valves, and that the embolus passed through the capillaries of the lung. While in this experiment the embolus caused merely infarction, it is probable that infarction from a bacillary embolus would induce an ulcerative endocarditis analogous to that in man. Septic endocarditis seldom occurs, because vessels in the valves are rare. Their presence is a sign of atavism, entailing the predisposition to ulcerative endocarditis. Development of old valvular lesions into septic endocarditis is due to formation of vessels in the valves, from the previous endocarditis. Mechanical injury of the valve tissue is not indispensable for production of endocarditis. Bacteremia alone does not cause endocarditis unless there are microscopic bacillary emboli in the blood. Only the ulcerative form presents a true infectious endocarditis. Other forms should be called endocardosis, since there is no inflammation of the valves; only changes of toxic origin.

Gonococcal Process in Spermatic Cord. H. Boshouwers.—p. 1068.

Prolonged Vascular Spasm After Trauma.—Finaly reports three cases of acute gangrene after a bullet wound or contusion; in two it developed in nineteen and twenty-nine hours. The disturbances spread also proximad from the site of the trauma, and the limb was extremely tender above and below, the tenderness stopping proximad at a circular limit. The disturbances subsided spontaneously in one case after removal of the bullet which had bruised the femoral artery. The continuous spasm of the vessels seemed to be a kind of traumatic neurosis in patients under 20.

Error in Urine Test for Sugar.—Van Bemmel found in 5 per cent of a recent hundred subjects that while a positive response was obtained with the Nylander test, on shaking the test tube the sediment dissolved, the reaction thus becoming negative. The Fehling test had been constantly negative in these cases. He warns that this false positive reaction might prove misleading in patients known to have had glycosuria in the past. Shaking the test tube (1 part Nylander reagent to 10 parts urine and boiling for three minutes) may spare such patients unnecessary diet restrictions.

Erroneous Therapeutic Principles. A. Clopatt.—p. 142.
*Determination of Size of Erythrocytes. E. Gustavson.—p. 152.

Hereditary Pseudohemophilia.—Willebrand describes a family with not less than twenty-three bleeders among the sixty-six members in four generations. The coagulation time was normal, but the bleeding time was extremely long in the grave cases, and the Rumpel-Leede phenomenon was pronounced. The clinical picture resembled that of Weil's disease although certain features differed, suggesting some functional disturbance in the thrombocytes plus a general lesion of the vessel walls. The thrombocytes numbered from 55,000 to 450,000. The eosinophils ranged from 1 to 14 per cent, the lymphocytes from 25.3 to 61.3 per cent, and the neutrophils from 35 to 65.4 per cent. He queries whether this may not represent a new nosologic type of hemorrhagic diathesis. The graver forms were in women and proved fatal in five. None of the male members died from this cause. Transmission seemed to be in the female line. Nineteen cases on record are summarized.

Syphilis and the Kidneys.—Tallqvist found no evidence in twenty-three cases of kidney disease in syphilitics that syphilis could be incriminated for nephritic changes in the kidneys. In nine cases the nephrosclerosis was of a severe progressive type, and the syphilis averaged twenty-seven years' duration. In two cases acute syphilitic nephrosis developed in recent infection; one recovered completely under specific treatment, and the other was much improved but failed to complete the course. Ordinary dietetic-hygienic measures in these cases had had very slight effect. In six chronic nephrosis cases, the syphilis seemed to have been the main factor, and all improved more or less under specific treatment according to the date of the primary infection. Exceptional caution is required in treating syphilis involving the kidneys. The doses should be small to begin with, not over 0.15 Gm. of neoarsphenamine, and the urine frequently supervised.

Size of the Erythrocytes.—Gustavson reproduces the blood findings as estimated by Löwy's method (described in these columns, June 20, 1925, p. 1969). This method may aid the practitioner in detection of pernicious anemia, for example, in an early stage. Diabetic blood takes stains a little differently, and gives a better contrast than normal blood in applying the Löwy method, as Taubmann recently announced.

The Dose in Sanocrysin Treatment. T. Begtrup-Hansen.—p. 278.
To Improve Tuberculosis Statistics. Kjer-Petersen.—p. 282.

Metal Salts Therapy.—Walbum's extensive research in this line with fifty different metals has confirmed the principle that the dose must be such as to stimulate production of antibodies while too small to stimulate the growth of bacteria. Combining with a vaccine the optimal dose of one of the few metals which displayed a protective and curative action, he was able to protect guinea-pigs against infection with tubercle bacilli and cure the established disease. The combination of vaccine and metal salt also protected mice against ratin infection, and protected tuberculous guinea-pigs against tuberculin shock. Manganese and beryllium proved most effectual in his experience. He assumes that antibody production is of enzyme nature, and thus can probably be influenced by catalytic phenomena.

Neoglucose.—This report states that there does not seem to be any production of the "new" form of glucose during fermentation of alpha and beta glucose.

The Insulin Complement.—Lundsgaard and his co-workers have found in their further research on the element in muscle tissue which, associated with insulin, transforms alpha and beta glucose into neoglucose, that it is not identical with Meyerhof's muscular coferment. It cannot be obtained from muscle tissue by water extraction, and it does not stand heating to 70 C. for two minutes. As its presence cannot be demonstrated in the juice obtained by pressure from muscle tissue, the insulin complement must be bound to the intact cell structure. It is found in both cold-blooded and warm-blooded animals.

DIAGNOSIS IN ORTHOPEDIC SURGERY *

FRANK R. OBER, M.D.
BOSTON

The orthopedic surgeon of today is well trained in the application of therapeutic measures to prevent and relieve deformity, but he is often faced with problems which have not been properly solved or which have been solved only after considerable injury has been done to important structures and he is expected to do the impossible in the restoration of function. Some of the reasons for this are wrong diagnosis, late diagnosis, snap diagnosis or the diagnosis of hysteria.

Musser[1] says, "Success in treatment requires both accuracy and completeness in diagnosis," and "Partial knowledge of a case differs in degree only from ignorance." To my mind these two sayings are as true today as they were twenty-five years ago, and they should make us pause and ask ourselves whether or not we are endeavoring to do everything in our power to locate and discover the trouble with many of our patients in order that they may get the benefit of the best modern knowledge.

Most weaknesses in solving problems in diagnosis are due to:

1. Bad elementary training.
2. Insufficient knowledge of the fundamental subjects in medicine.
3. Lack of proper hospital training.
4. Incomplete physical examinations.
5. Failure to make a thorough search for the cause of the ailment.
6. Premature selection of a specialty.
7. Dependence on the roentgen ray alone.

1. Bad elementary training begins with the child's early education, and the results apply not only to medicine but also to any other occupation that the person may select. Those of us who come in contact with medical students realize early that there are two outstanding things in which they appear to be deficient: First, they lack the faculty of making accurate observations, and, second, they lack the ability to reason or think out their problems in a straight and logical manner; on the other hand, their memories for a short period of time are usually good. It is rather late, when a student enters on a professional career, to expect his teachers to train him to study, observe and reason if he has not been taught to do so before. When he arrives at the clinical part of his course he is more or less deficient in those basic fundamentals which are so essential in making a diagnosis; i. e., the power to observe and reason.

2. Making an accurate diagnosis of many orthopedic conditions is based on a sound knowledge of anatomy, physiology and pathology. In fact, nearly all orthopedic conditions are due to pathologic disturbances of structure and function. How many third and fourth year medical students are there who can name, locate and give the function of the principal muscles which control the ankle or hip joints? Is it not possible to obtain a closer association of these subjects and the clinical subjects in the medical schools?

3. Does the average intern in the average hospital receive any systematic training, from members of the visiting staff, in the art of examination and diagnosis? Is it not a part of our duty to see that the young men who come to us for help and inspiration are properly trained?

4. Most orthopedic problems are individual; therefore, each patient should be considered as a health unit and examined accordingly. Too many are satisfied with making an examination of the local condition when a more searching one would have revealed, perhaps, the key to the local disease. If we are not competent to do all that a complete examination involves, we should at least have sufficient knowledge so that the patient may be referred to some one who is capable of doing what is necessary.

5. Many diseases are easily diagnosed, but successful treatment often depends on finding a cause. Arthritis is an example. Of course, there are a great many diseases whose causes are unknown and can be determined only by persistent research.

6. Premature selection of a specialty is not uncommon among medical students. Many of them, early in their medical course, determine on the special line they wish to pursue, and, having made their selection, the inclination must be for them to neglect important courses, not realizing that every specialty in medicine may often be interlocked with some or all of the others. The result of this must be to produce a man with very narrow limitations in his line because much that is fundamental has been cast aside. How can one educated in this way become a good diagnostician?

7. Depending on the roentgen ray to make a diagnosis is a fault in a good many clinics and has been the cause of a good deal of harm. In the first place, pathologic changes may be present for many days or even weeks before the roentgen ray will reveal them. In the second place, there are so many lesions that give similar appearances in the roentgenogram that a proper diagnostic interpretation cannot be made. The r

[1] Musser: Medical Diagnosis, ed. 2.

gen ray is a valuable aid in diagnosis; so is the clinical thermometer; but no one would think of depending on this for a diagnosis.

Hysteria as a diagnosis is a very dangerous one to make, and the burden of proof should fall on the one who makes it. Many patients have this diagnosis thrust on them as a result of a poor examination or an improper assembling of pathologic data. The following is a case in point:

M. B., a girl, aged 16, seen in September, 1925, had had a difficult birth with instruments, and began walking at the age of 2 years. It was noticed that she had difficulty in using the left arm and leg. She did fairly well up to the age of 13, when she fell, striking her head; she was not unconscious, but there were contusions on the head. The right side became affected after the fall, and the left side was worse than formerly. There was some disturbance of sensation and some loss of control of the bladder and rectum. Sensation had gradually improved, and control of the bladder and rectum had returned. Examination showed a quadriplegia more marked on the right side, bilateral equinus, and some contracture of the shoulders and wrists. There were definite sensory disturbances in the legs. The eye grounds and eye reflexes were normal, the abdominal reflexes absent, all tendon reflexes increased, bilateral Babinski and ankle clonus present. Roentgen-ray examination showed an old fracture of the odontoid process, with a slight backward displacement of the first cervical vertebra. Combined puncture showed no block in the cerebrospinal canal. The basal metabolism was — 41 per cent. There was normal mentality for the age of 16, but the patient's size was that of a child of 9. The roentgen-ray report was, old injury of the cervical spine. The clinical diagnosis was paralysis resulting from an old injury to the cervical spine. The admitting diagnosis was hysteria.

Making a snap diagnosis is an error into which we may fall, and is oftener wrong than right. It is made usually after a very superficial examination or none at all. The most to be said for it is that it is dangerous and not fair to the patient.

Inability to make a diagnosis may be due to absence of localizing symptoms, an atypical cause of a disease, or lack of knowledge of the nature of the disease.

Late diagnosis is often dependent on a lack of scientific knowledge, improper preparation of a case, insufficient data, inability to assemble facts, lack of cooperation by the patient, or carrying out expectant methods too long before reviewing developing signs and symptoms. A diagnosis of joint tuberculosis is made quite often, on symptoms and a few signs, and the patient is so treated over a long period because some one has said that in obscure joint affections a guess on tuberculosis would be right 80 per cent of the time. Are we justified in treating the other 20 per cent as tuberculosis?

Early diagnosis should be our aim, and everything should be done to convince the patient that he will be spared pain, deformity and long drawn out treatment if he will cooperate with us.

There are four diseases which are often diagnosed late and which supply us with more cripples than all the other orthopedic conditions combined. They are acute osteomyelitis, acute poliomyelitis, bone and joint tuberculosis, and chronic arthritis.

Acute osteomyelitis is usually diagnosed as "acute rheumatism" or acute lymphangitis, and is allowed to go on until the patient becomes seriously ill and great bone destruction takes place. The diagnosis must be made on the history, the general and acute local symptoms present, which are out of all proportion to the extent of the lesion, the white blood count and loss of function. Roentgen-ray findings are of no value.

Poliomyelitis usually is seen late by the orthopedic surgeon; but since the deformities caused by this disease may be disabling, we as a group ought to be interested in putting out propaganda for diagnosis in the preparalytic stage, because in most cases this can be made. Pathologically, the meninges are the tissues that are primarily invaded, and the early signs are mental irritability, stiffness of the neck, and headache. These, when associated with signs of constitutional disturbance, should lead one to do a lumbar puncture. Lumbar puncture not only confirms the diagnosis but probably has a therapeutic value. The following case is illustrative of this point:

E. L., Sept. 7, 1925, complained of severe headache, fever, and soreness of the legs, of fifteen hours' duration. The temperature was 102; pulse, 100. General examination was negative except for a slight tenderness of the lower extremities, a little stiffness of the neck, photophobia, and a questionable Kernig sign. The knee jerks were hyperactive. Lumbar puncture showed the spinal fluid under considerable pressure, a cell count of 600, and no organisms. The next morning the temperature had dropped, and the headache had nearly gone. There was a slight rise in the afternoon temperature, but no more headache. The diagnosis was poliomyelitis. No paralysis developed.

The problem of arthritis has not been solved, but the percentage of cases relieved at the present time is a great deal higher than it was ten years ago. We should have no sympathy for those who place this disease in the large group of the incurable without making any effort to attempt a cure. Too often are the prodromal signs and symptoms ignored or treated with a few doses of acetylsalicylic acid when active measures will check them or even result in a cure. Patients who complain of soreness in their muscles or slight early morning stiffness in a few joints should not be put off with reassuring advice but should at once be shown the urgent necessity of a thorough and complete examination in order to locate the source of their troubles. Since the beginning of the theory of focal infections, many patients with arthritis have been cured; but our examination should not stop with infected teeth and tonsils. The examination should include the metabolism rate, teeth, tonsils, sinuses, genito-urinary tract, throat, ears and chest, and a great deal of attention should be paid to the gastro-intestinal tract. Barium meals may be necessary, an examination of the stools should always be made, and we shall be surprised to find how many of these arthritic patients have a mild, low grade constipation which, when properly treated, often results in a disappearance of arthritic symptoms.

J. F., seen in October, 1923, had had slight discomfort in both knees for one year and had an area of tenderness over the medial aspect of both knees. The knees had never swelled. The patient had a sensation of stiffness in the ankles, elbows and fingers at times in the morning. Examination of the knees showed nothing abnormal except in the infrapatellar fat pads, which were thicker than normal. All other joints appeared to be normal. The abdomen was low and prominent. A general medical examination was advised. This was not done until January, 1924, and revealed nothing abnormal except marked constipation. At that time there was considerable pain and swelling in both wrists, the tendons and joints being involved. There was pain in both elbows, which were sensitive on extreme extension. The teeth and tonsils were normal. In April, pain and swelling developed in the ankle joints, shoulders, neck and knees. The arthritis was completely relieved by a low carbohydrate diet, oil cathartics, intestinal massage and irrigations.

If this patient had cooperated during the early part of her attack and vigorous measures had been pursued, she would no doubt have saved many months of treatment and disability.

Bone and joint tuberculosis can be diagnosed early in a very high percentage of cases. Many joint conditions are diagnosed tuberculous, and are so treated over a long period. Such cases are often presented at clinics as cures, but when some one present wishes to know how the diagnosis was made, an embarrassing moment ensues if we are honest.

It has long been taught that positive proof of tuberculosis is made only when pus or fluid obtained from the affected area shows the tubercle bacillus, or material obtained shows under the microscope a lesion characteristic of tuberculosis, or suspected material injected into a guinea-pig produces tuberculous lesions. When joint tuberculosis is suspected, a thorough history should be taken and an examination made to determine whether or not there is a primary focus, it being remembered that tuberculosis is primarily a disease of the lymphatic system. Such an examination should include a roentgen-ray examination of the chest, a tuberculin intradermal test, and also a focal tuberculin test; roentgenograms of the joints should be taken, and when the evidence is not sufficient, a biopsy should be done. In doing a biopsy a generous amount of pathologic tissue must be removed from the affected area, sectioned very carefully, and many sections should be searched for the presence of tubercles. Some of this tissue should be thoroughly macerated and injected into the subcutaneous tissue of the thighs of two guinea-pigs (one pig may die before tuberculosis develops). This method will diagnose very early a great many doubtful cases and is preferable to expectant methods which must necessarily cover long periods of time and often cause considerable injury to tissues as a result of long immobilization. If the lesion is tuberculous the joint may be treated by heliotherapy with an earlier resumption of function or in adults an excision or fusion may be done.

J. E. S., aged 48, seen in May, 1919, had had trouble with the left knee for fifteen years. Six years before examination a cast had been worn for four months, and the patient had never been able to walk without a cane since that time. Examination showed a very tender knee permanently flexed at 45 degrees with moderate swelling and muscle spasm, and no motion present. Roentgen-ray examination was negative. The patient was treated in a traction knee splint with considerable relief for four years. Roentgenograms taken at intervals were always negative. The patient reported in October, 1923, that for the past few months the symptoms had increased and become more acute The patient consented to have the knee operated on. October 17, 1923, the knee joint was opened by a U-shaped incision. The capsule was dense, thick and fibrous; fibrous adhesions were present throughout the joint. These adhesions were broken up, and a small tuberculous cavity containing tuberculous pus was found in the center of the lateral condyle of the femur. A formal excision was then done. The patient made an excellent recovery and has remained well ever since.

If that knee had been treated by modern methods, the joint would have been explored, an early diagnosis made, and years of suffering and disability would have been prevented.

My final plea is for better medical education, more progress in general medical teaching, more complete physical and chemical examinations, and an endeavor on our part to make our diagnosis as early in the course of disease as possible.

234 Marlboro Street.

TYPES OF NEUROSYPHILIS IN RELATION TO TREATMENT*

HENRY A. BUNKER, Jr., M.D.
NEW YORK

It is a well established fact that syphilis of the nervous system varies in the widest possible manner in its amenability to treatment. At one extreme we have those cases of neurosyphilis in which the spinal fluid becomes completely and permanently negative after a few intravenous injections of arsphenamine, and sometimes even spontaneously without treatment; while at the other end of the scale stand those cases which prove intractable to all ordinary methods of antisyphilitic treatment, and which in general develop sooner or later into outspoken cases of tabes or general paralysis. Now it is not too much to say that some years ago—before the introduction of intraspinal therapy and its modifications in the form of intracisternal and intraventricular injections,[1] and especially tryparsamide [2] and the malaria treatment [3]—it was not of especial practical importance to discriminate between these two broadly divisible types of neurosyphilis; for the vast majority of cases of the completely refractory type were doomed from the outset, so that their nonrecognition could usually in no way prejudice their ultimate outcome, while the patients of the less intractable type, on the other hand, could in most instances be counted on to do well under routine (intravenous) antisyphilitic therapy. But the advent of new and more efficient methods of treatment would seem to place the matter in a rather different light. For, if advantage is to be taken of these newer methods, it becomes of the highest practical importance to identify at the outset those very cases of neurosyphilis which formerly resisted all therapeutic efforts of a less intensive character, but which can now be handled with some real degree of success by means of these more effective methods of treatment.

If it be granted that such a necessity as this has come into being, it only remains to consider the means of recognizing the cases of neurosyphilis for which ordinary treatment will probably prove useless. It is not here a question of the diagnosis of syphilis in a given patient, nor even of the diagnosis of neurosyphilis itself, for failure in either of these two respects does not come within our present purview; our problem deals only with the patient in whom syphilitic involvement of the nervous system is known to be present, the question being: What, then, is the proper treatment for that patient?

It might here be well to state that the subjoined remarks are made from a single restricted point of view—from the point of view, that is, of one who has had occasion of late to treat numerous cases of outspoken general paralysis in which the existence of neurosyphilis had previously been proved, but for which nothing had then been done that might have been successful in preventing the evolution of an asymptomatic case of neurosyphilis, or of an early case of general paralysis, into a fully developed example of that disease, as the cases presently to be cited will serve to illustrate.

For the purposes of the purely practical discussion here in question, let us dispense in the first place with all attempts at distinguishing between the parenchymatous and the meningovascular forms of neurosyphilis; for these are terms based on the data of pathologic anatomy, and have no very immediate cogency from a clinical and therapeutic standpoint. It should be remembered in this connection, for example, that just as disturbance of the pupillary reaction to light, or indeed the Argyll Robertson pupil itself, may be present in any form of neurosyphilis, so likewise the symptoms presented by the patient often similarly fail to serve as a basis for distinguishing between meningovascular and parenchymatous involvement of the nervous system. For we do not know the pathologic condition that specifically lies back of the individual symptoms that these various patients present; we cannot prove a correlation between the symptoms and the structural changes present in the meninges and the nervous tissue. We can only say, as Dunlap[4] has carefully stated it, that a meningitis—differing in certain details, it is true, but similar in its essential characters—is common to both the meningovascular and the parenchymatous types of cases; and that this may perhaps be in part the reason why the symptoms themselves offer no criterion for clinical differentiation. In illustration of this may be mentioned the symptoms that I[5] recently enumerated as characterizing the earliest onset of general paralysis in a series of cases of that disease: hardly one of the symptoms there described but might equally well be observed in patients with a meningovascular rather than a parenchymatous form of neurosyphilis.

If the symptoms of the patient are often of little avail in making a differentiation that is based on histologic grounds, the same may be said of the spinal fluid findings, for these offer, in and of themselves, no very certain indication of the character of the neurosyphilis with which we are dealing. Speaking very generally, it may be said that a Wassermann reaction that is negative in 0.2 cc., and particularly in 0.5 cc., of spinal fluid tells fairly strongly against the paretic form of neurosyphilis, at least in cases previously untreated; but the converse is not necessarily true. Moreover, many cases of tabes, as is well known, may at some stage of the disease present a weakly positive or even a wholly negative Wassermann reaction in the spinal fluid. And it might be added that a colloidal gold curve of the nonparetic type speaks more strongly against a diagnosis of general paralysis, as Solomon[6] was among the first in this country to point out, than does a curve of the paretic type speak necessarily in favor of that form of neurosyphilis or against the presence of the meningovascular type of the disease; yet this rule, too, is not altogether without exceptions.

The clinical differentiation, then, between the meningovascular and parenchymatous forms of neurosyphilis not only often offers considerable difficulty, even to the point of being sometimes quite impossible during life, but, considered from the strictly practical standpoint of the proper treatment of the neurosyphilitic patient, is not needful and serves no end that cannot better be met by other means. For what I hope to make clear is that from this single therapeutic standpoint the nomenclature employed is unimportant in comparison with the necessity for controlling the treatment of the neurosyphilitic patient at all stages by repeated examination of the spinal fluid. In other words, it does not here much matter what nosological type of neurosyphilis—meningovascular or parenchymatous, mesodermal or ectodermal—the patient is suffering from, and what label we may elect to apply to it; what does matter is whether our treatment is proving efficient in the given case of neurosyphilis, regardless of its label, as indicated by a definite and progressive effect on the spinal fluid abnormality. Nor can this crucial point be determined without the repeated examination of the spinal fluid, as treatment proceeds, to which reference has just been made. Indeed, one might say that, in the treatment of the neurosyphilitic patient, a single spinal fluid examination is of about as much significance as a single temperature reading in an acute infection would be.

ILLUSTRATIVE CASES

In illustration of the necessity for such a procedure, and of what may happen when it is not carried out, may be cited briefly the following four cases:

Case 1.—There was a chancre in January, 1916, followed by secondaries, five injections of arsphenamine and six mercury treatments were given. The patient had headaches in April. Lumbar puncture yielded 700 cells. The Wassermann reaction was strongly positive. Nine arsphenamine treatments were given. In August, 1916, there were 180 cells, and the Wassermann reaction was strongly positive. Objectively, there was involvement of the second nerve bilaterally and eighth nerve unilaterally. Thereafter more than 150 arsphenamine injections [illegible] given intravenously. There were mental sy[illegible] August, 1923. The patient was committed in [illegible] with general paralysis.

[illegible] that was early found to have neurosyphilis, [illegible] might have been considered by the subsequently published criteria of Moore[7] to be of the parenchymatous type, especially in the light of the spinal findings still present on the occasion of the second lumbar punctur[illegible] even years later the patient did actually develop an [illegible]oubted case of general paralysis, which the rather large amount of routine intravenous medication he received had been powerless to avert. This would indicate that, even if, for the protection of the patient, a probably highly resistant form of neurosyphilis had not at the beginning been assumed to be present until proved otherwise, a third lumbar puncture done at the end of six months would have undoubtedly revealed the fact that the treatment employed, though effective against the symptoms, was having little or no influence on the spinal fluid findings. And this, by the way, is suggestive of how misleading and of little value symptomatic amelioration may be in the absence of concomitant improvement in the spinal fluid picture. Indeed, it has been our frequent observation that patients with fully developed general paralysis, even, may experience a temporary improvement and arrest of their symptoms under intravenous treatment with arsphenamine; but the latter exerts little or no influence on the spinal fluid abnormality in such cases, and in fact the symptomatic improvement is sooner or later succeeded by relapse and the subsequent commitment of the patient.

Case 2.—There was a chancre in September, 1917. The patient had a slight sore throat. Neo-arsphenamine, twelve treatments, and mercury, eight, were given. No further treatment was administered till December, 1922. At that time the patient presented somewhat sluggishly reacting pupils; diminished and unequal knee jerks; absent right ankle jerk, and absent abdominals. The patient was given neo-arsphenamine, ten treatments, from January to April, 1923. There were beginning mental symptoms from January, 1923, but grossly from January, 1924. Lumbar puncture in March, 1924, yielded 50 cells. The Wassermann reaction was strongly positive in 0.6 cc. and moderately positive in 0.4 and 0.2 cc. The gold curve was of the paretic type. The patient was committed, April 29, 1924, with general paralysis.

[7] Moore, J. E.: Studies in Asymptomatic Neurosyphilis, II. The Classification, Treatment and Prognosis of Early Asymptomatic Neurosyphilis, Bull. Johns Hopkins Hosp. 33: 231 (July) 1922.

In this case the diagnosis of neurosyphilis through the help of a spinal fluid examination was not made until fifteen months after the discovery of highly suggestive neurologic signs in a known syphilitic patient, and one year after completing a course of ten intravenous injections of neo-arsphenamine. When treatment was then resumed, it was still intravenous only and was shortly interrupted because the patient was then almost on the verge of commitment.

Case 3.—The patient had a chancre in 1908. Two years' treatment with mercury was given. In 1919, twelve treatments with arsphenamine were given. In September, 1922, the pupils were markedly unequal, and the spinal fluid showed a high cell count. The Wassermann reaction was strongly positive, and there was a paretic type of gold curve. Thereafter till November, 1923, eight intraspinal injections of neo-arsphenaminized serum were given. There was improvement in weight and in general well being, "but there was never any change in the spinal fluid serology." There was a slight but rather definite personality change in June, 1923. The patient abandoned treatment in November, 1923, but reappeared in March, 1924, with marked loss of weight. The patient refused intraspinal treatment, but took sulpharsphenamine twice weekly until May, 1924, with physical improvement. There were definite mental symptoms in June and July, 1924. The patient was committed, Aug. 26, 1924, with general paralysis.

This case, well handled so far as the patient made it possible, carries the argument one step further. It is to be noted that eight treatments by the Swift-Ellis technic carried out at (presumably) three week intervals were without influence on the spinal fluid picture, a fact in itself pointing to a probably obstinate type of nervous system involvement, subsequently confirmed by the later appearance of unmistakable general paralysis. This situation would accordingly seem to call for the adoption of one or more of the four following procedures: continuation of the Swift-Ellis technic but at shorter intervals, its supplementing with intracisternal injections,[1] a thorough trial of tryparsamide, and treatment with malaria. Indeed, I believe it not too radical, in view of the time-conserving nature of the malarial treatment, it being completed within two weeks, to employ that mode of therapy at the outset in patients in whom the persistence of strongly positive spinal fluid findings after a thorough trial of arsphenamine intravenously makes the presence of a refractory form of neurosyphilis distinctly a possibility. For, although it is true that the malaria treatment influences the spinal fluid abnormality either little or only very gradually,[8] its effect on the underlying disease is in many cases undoubtedly considerable;[9] and this effect is brought to bear with such economy of time as to allow the more ample opportunity for the subsequent use of more protracted modes of treatment, such as tryparsamide and intraspinal injections.

Case 4.—Within two years of a chancre there was an attack of unconsciousness, the spinal fluid showing many hundred cells and a positive Wassermann reaction. Three years later there were Argyll Robertson pupils; the knee jerks were greatly diminished; there were definite ataxia, some speech defect, marked tremor of the circumoral muscles, and some memory defect perceptible to the patient. After a course of intravenous injections of arsphenamine, some improvement in memory defect was alleged by the patient.

In this case the omniscience of "hindsight" is less in evidence, the problem being a present one. This patient exhibits symptoms so suggestive as to place the burden of proof on him who says that he does not present a fairly early case of general paralysis, even in the absence of a spinal fluid examination. Which, then, is the better for the patient: To ignore the possibility that his may be a case of general paralysis, only to discover too late that the process was in fact a "malignant" one; or to treat the patient, beginning now, as though his case were of the "malignant" type, so that if in reality "benign," so much the more readily will some therapeutic result be achieved, while, if "malignant," only in the most intensive treatment possible may hope for a favorable outcome lie?

The deduction that seems inescapable from considerations such as the foregoing is that it is above all important to determine whether the treatment given the patient is accomplishing the purpose intended, regardless of how the case may be classifiable from a purely pathologic standpoint. In other words, it does not practically matter, as indeed we have already said, what nosological type of neurosyphilis the patient is suffering from nearly so much as it matters what answers we can give, in the individual case, to such questions as these: Is the patient receiving the right kind of treatment and the right amount of treatment, as judged by a definite effect on the spinal fluid findings? If this effect fails to come about after a conscientious effort to produce it, is it not time to alter the treatment accordingly—to make it more intensive or to adopt a different therapeutic agent? In case of doubt on the score of the sufficiently favorable response of the patient, should it not be assumed for his protection that he presents a refractory form of neurosyphilis for which more active therapy is needed, until the contrary can be proved?

Speaking concretely, a patient known to have neurosyphilis (whether asymptomatic or not) should receive a course of at least twelve weekly intravenous injections of arsphenamine or of neo-arsphenamine. At the end of such a course it is absolutely necessary to discover what effect this minimum treatment has had on the spinal fluid. Numerous cases clear up completely under this amount of therapy, or give promise of doing so under some further systemic treatment. Others may show a certain amount of modification of the spinal fluid picture; and here the question whether a course of intraspinal injections or several courses of tryparsamide is not greatly preferable to a continuance of intravenous arsphenamine injections immediately presents itself. Needless to say, rigid control of the treatment by means of repeated spinal fluid examinations remains imperative. Still other cases will show no change whatever in the spinal fluid, so far as the Wassermann reaction and the colloidal gold curve are concerned; and in these it is evident from the outset that the most intensive methods of antisyphilitic treatment will have to be adopted and adhered to. Indeed, there is some reason to believe, as has already been suggested, that in these known pernicious cases two weeks given over to malaria may be worth several months of the intraspinal or tryparsamide therapy with which the malaria can be immediately followed up.

Stokes[10] has recently spoken trenchantly of the necessity for individualizing the treatment of the tabetic patient. How can it be that the need is less crying for individualizing the treatment of the neurosyphilitic patient in general? If this is done in somewhat the manner that has been roughly indicated in the foregoing, it is not impossible that the more disastrous results arising out of neurosyphilis may be averted more frequently and successfully than is now the case.

SUMMARY

1. The differential diagnosis between the meningovascular and parenchymatous types of neurosyphilis is often difficult and sometimes impossible; for the symptoms (if present) may not infrequently fail to serve this end, while the spinal fluid findings provide evidence that may or may not be of value.

2. From a practical standpoint, however, the nomenclature employed is quite unimportant in comparison to the necessity for controlling the treatment of the neurosyphilitic patient by means of repeated examinations of the spinal fluid. For the disappearance merely of the symptoms does not represent the end sought for if the spinal fluid findings continue positive; neither symptoms nor pathologic condition of the spinal fluid must remain present if the actual aim of therapy is to be achieved. And if such a result is not being brought about by the method of treatment in use, then that treatment is obviously not the right treatment for that particular case, and must be changed either in intensiveness or in kind rather than adhered to in the face of its proved inefficacy.

3. It is suggested that in at least the serologically intractable cases, the presumable preparetic patients, malaria finds a place as a therapeutic agent of the first rank, since it acts against the neurosyphilitic infection in a definite if little understood manner, and with an economy of time that allows ample opportunity for the subsequent use of more time-consuming specific methods.

[10] Stokes, J. H., and Schaffer, L. W.: Clinical Management and Response of Tabetic Patients, J. A. M. A. **85**:1271 (Oct. 24) 1925.

Relative Value of Various Antiseptics.—The antiseptics tested have included alcohol, iodine, mercuric chloride, mercurochrome, acriflavine, protargol, albargin, gentian violet, neo-arsphenamine, and hexylresorcinol. Pieces of spleen of a freshly killed rabbit were placed one minute in a suspension of *Staphylococcus aureus*, and then put in graded solutions of the antiseptic for twenty minutes. In the majority of instances, particularly in the case of several of the newer antiseptics, bacteria proved decidedly more resistant than cells. The most favorable results were obtained with iodine, mercuric chloride, and neo-arsphenamine. Acriflavine, gentian violet and mercurochrome gave the least favorable results. A second series of experiments was carried out in which the antiseptic was added directly to the plasma culture medium. Inhibition of bacterial growth was seen in dilutions of plasma of 1:30-40,000, while the cells were only slightly damaged by these dilutions. The findings with acriflavine and mercurochrome were quite as unfavorable as in the other tests. In general the tests suggest that in so far as the direct action on cells and staphylococci are concerned, some of the classic antiseptics, such as iodine and mercuric chloride, approach nearer the ideal than certain of the newer preparations, and that neo-arsphenamine might be hopefully employed in generalized bacterial infections as well as in certain protozoan diseases.—Lambert, R. A., and Meyer, J. R.: *Proc. Soc. Exper. Biol. & Med.* **23**:429 (March) 1926.

ADVANCED MENINGOCOCCUS MENINGITIS

TREATMENT BY COMBINED VENTRICULAR, CISTERNAL AND LUMBAR PUNCTURES *

MAX MINOR PEET, M.D.
ANN ARBOR, MICH.

The introduction by Flexner, in 1907, of a curative serum for epidemic cerebrospinal meningitis has reduced the mortality under the most favorable conditions to a level now variously estimated at from 20 to 25 per cent. This relatively high death rate may be due to three factors: first, extreme virulence of the organism, producing a fulminating meningitis; second, an organism of different type from that used in preparing the antimeningococcus serum, and, third, late recognition of the disease. The latter is certainly the more common, since the fulminating type is rather rarely seen and the standard serums now on the market are polyvalent.

The routine administration of antimeningococcus serum by lumbar puncture has given gratifying results only in early cases. In late cases in which treatment was by lumbar puncture, the mortality has been very high, and in those patients who survive, hydrocephalus and other serious sequelae are comparatively common. These discouraging results are often due to spinal subarachnoid or ventricular block. It is my purpose in this paper to emphasize the value of ventricular and cisternal punctures in advanced meningococcus meningitis, illustrating with a typical case.

Ayer[1] has shown that, without spinal block, 20 cc. of serum introduced by lumbar puncture does not reach the cisterna magna during the period of injection; likewise, 30 cc. of india ink injected into the lumbar subarachnoid space of a cadaver barely blackens the base of the brain. In contrast to these findings, the introduction of a similar amount of india ink by cisterna puncture stains the entire cerebral cortex as well as the basilar cisterna. Since the meningococcus reaches the cerebral subarachnoid space by way of the nasopharynx and involves the spinal canal secondarily, it seems logical to introduce the curative serum by a route that will insure maximal concentration, and maximal distribution over the areas first infected.

Puncture of the cisterna magna gives this optimal route and has been shown to be a safe and efficient procedure in the hands of those who understand the anatomy of the region. We therefore believe that any patient with epidemic meningitis who is not showing satisfactory progress under lumbar therapy should be treated by the introduction of serum directly into the cisterna magna. Indeed, certain authors have suggested the latter procedure as the routine method of treatment for all cases, discarding lumbar puncture as definitely less efficient.

However, it is in the presence of a spinal subarachnoid block, a not uncommon complication in late cases, that cisterna puncture is not only indicated but imperatively demanded. The first application of this method was reported by Wegeforth, Ayer and Essick.[2] Unfortunately, the procedure was used too late in the disease to save life. Later, Ayer[1] reported the first successful case in which, as in the one reported in this communication, the patient also developed ventricular infection requiring the intraventricular injection of serum. Subsequently, Mitchell and Reilly[3] reported the successful treatment by cisterna puncture of a 4 months old infant with spinal subarachnoid block. Ebaugh[4] had five complete recoveries in eight cases of advanced *meningococcus meningitis*. A successful case in which treatment was by cisternal-lumbar irrigation is referred to by Ayer.[5] That cisterna puncture is potentially dangerous is recognized by all, but in the hands of those familiar with the anatomic structures involved, it has proved a safe procedure. This is shown by Ayer's[6] compiled statistics of 1,985 punctures and Ebaugh's[4] later figures of approximately 1,550 personally performed punctures. About 1,000 of the latter are included in the former report. They were performed for a variety of conditions, principally for the treatment of cerebrospinal syphilis and for the diagnosis of spinal cord tumors, only eleven cases of meningococcus meningitis being included.

---

[2] Wegeforth, Paul; Ayer, J. B., and Essick, C. R.: The Method of Obtaining Cerebrospinal Fluid by Puncture of the Cisterna Magna (Cisterna Puncture), Am. J. M. Sc. **157**:789 (June) 1919.

Ventricular puncture for the introduction of antimeningococcus serum, first brought into prominence by Cushing and Sladen,[7] has proved of great value. In fact, Howell and Cohen[8] now consider this route much superior in infants to the more commonly used lumbar puncture. They also recommend cerebral subarachnoid injections through the anterior fontanel. They show that a large number of apparently cured patients are found, on follow up examination, to develop hydrocephalus.

The use of alternate cisternal and lumbar puncture to prevent subarachnoid block has been suggested by Ebaugh. Combined ventricular, cisternal and lumbar punctures in the presence of both cerebral and spinal block have been used successfully by both Ayer and myself.

A typical example of the complication of ventricular and spinal subarachnoid blocks in an advanced case of meningococcus meningitis with complete recovery and no evidence of hydrocephalus over two and one-half years later is here reported.

REPORT OF CASE

N. M. N., a girl, aged 8, seen June 8, 1923, with an unimportant family history and previous illnesses, was in semicoma, but when aroused was delirious. It was stated that she had been sick only twenty-four hours, but the mother was a Christian scientist, and the illness may not have been recognized until a serious condition developed.

The child was well developed and nourished; she was acutely ill, semicomatose, delirious and very restless. The head was sharply drawn back, the neck held rigid, and the spine kept in a mild opisthotonos position. The neck could not be flexed. Attempts to do so caused the child to scream and draw up the lower extremities. All reflexes were exaggerated. There was a bilateral Kernig sign. A small ecchymotic area, about 1 cm. in diameter, was noted on the right upper eyelid. Petechial hemorrhagic spots were present at the angle of the mouth and over the chest, abdomen and extremities, most marked in the bend of the elbows and knees. The pupils were somewhat dilated, but reacted to light. The child frequently rubbed her hands over her eyes, as if attempting to clear her vision. She was apparently blind, as no reaction was elicited by passing the fingers rapidly in front of the eyes. The ears, nose and throat were normal, except for enlarged tonsils. The tongue was dry coated and deeply furrowed. There was a bilateral cervical adenitis.

Lumbar puncture yielded a definitely yellowish, very cloudy fluid under marked pressure. Throughout the fluid were numerous large flakes of pus, similar to those seen in a thoracic empyema of several days' duration. Globulin and albumin were present in large amounts. Smears showed large numbers of intracellular gram-negative diplococci. The diagnosis of epidemic meningococcus meningitis was confirmed by culture.

On admission, the temperature was 101.4 F., the pulse from 90 to 110, and the respirations, 22. After a lumbar puncture with the withdrawal of 45 cc. of very purulent cerebrospinal fluid, 30 cc. of antimeningococcus serum was administered by the lumbar route. One hour later, the child was slightly more rational, complaining of very severe pain in the head. Five hours later, 30 cc. of serum was given intramuscularly. Codein hypodermically and chloral by rectum were required to control restlessness; 650 cc. of saline solution was given subcutaneously.

June 9, she was still irrational, but understood what was said to her. The temperature was 99, the pulse, 84, and respiration, 18. A slight chill was followed later by a temperature of 101.4 F., pulse, 120, and respiration, 20. Lumbar puncture was done at 11 a. m. The fluid was under pressure, but not so cloudy; 30 cc. of antimeningococcus serum was given. At 7 p. m., the temperature had risen to 104.4, the pulse was 112, and respiration, 20. A lumbar puncture was done, and 40 cc. of yellowish, cloudy fluid under pressure was withdrawn; 30 cc. of serum was given.

June 10, the condition was about the same. The temperature did not drop below 102 F. The patient did not recognize any one, but understood commands. A lumbar puncture was done at 11 a. m., with the withdrawal of 40 cc. of slightly cloudy fluid, with not much pressure; 30 cc. of serum was given. The temperature was slowly rising. The patient cried out on slight motion; she complained of severe pain in the head, neck and legs. At 8 p. m., the temperature was 103. At lumbar puncture, the fluid was not under pressure; it was slightly cloudy, with no organisms in the smear; 30 cc. of serum was given.

June 11, the patient was very drowsy, sleeping much of the time, but cried out at intervals. She was difficult to arouse, and did not respond to commands. The temperature was 104.4 F. The pulse was from 110 to 120, and respiration, 20. Cisterna and lumbar punctures were done at 11 a. m. The lumbar fluid was slightly cloudy and yellowish, with no pressure, only 20 cc. being obtained. No organisms were found on smear. A cisterna puncture with the lumbar needle still in place was done; 30 cc. of very cloudy, opal fluid under marked pressure was withdrawn. Fifteen cubic centimeters of serum was introduced by the lumbar route and 15 cc. through the cisterna puncture. The cisterna fluid differed markedly from that obtained by lumbar puncture and showed many organisms on smear. Both fluids gave a growth on culture. The temperature dropped to 100.8, the pulse to 105, and respiration, 20. The mental condition was about the same. The child was apparently sleeping, but talked almost constantly. At 7 p. m., the temperature was 103.4, the pulse, 120, and respiration, 25. A lumbar puncture, with the withdrawal of 35 cc. of slightly cloudy fluid, was done; 30 cc. of serum was given. No organisms were found on smear, but a culture later showed many colonies.

June 12, the temperature dropped steadily after the last puncture, reaching 99.8. It then rose in spite of the two injections of serum to 105.2. The general condition was unchanged. At 2 p. m., the temperature was 100. A lumbar puncture was done, 40 cc. of cloudy fluid being withdrawn. A smear showed organisms. Thirty cubic centimeters of serum was injected. At 5 p. m., the patient was weaker, and cyanotic under the eyes. A cisterna puncture was done, with the fluid under marked pressure and very cloudy and yellowish. There were many organisms in the smear; 50 cc. was withdrawn and 40 cc. of serum injected intercisternally. Lumbar puncture at the time of the cisterna puncture showed much less pressure, the spinal subarachnoid block still persisting. Twenty cubic centimeters of serum was given in the lumbar region.

June 13, the general condition was slightly better. The temperature dropped to 100 after the cisterna puncture of the previous day. A lumbar puncture at 11 a. m. yielded a cloudy fluid under slight pressure; 45 cc. was withdrawn, and 45 cc. of serum injected. Smears were negative. Cultures showed only two colonies. The mental condition was not improved. At 4: 30 p. m. a triple puncture—lumbar, cisterna and right ventricle—was done. The lumbar fluid was not under pressure and was cloudy; 20 cc. was removed. The cisternal fluid was under pressure, cloudy and yellowish; 40 cc. was withdrawn. The ventricular fluid, obtained by trephining the skull and puncturing the posterior horn of the right lateral ventricle, showed marked pressure after cisternal pressure had been completely reduced; 25 cc. of ventricular fluid was removed; it was slightly cloudy, colorless but showed many organisms on smear. Fifteen cubic centimeters of serum was introduced into the ventricle, 30 cc. into the cisterna magna and 15 cc. into the lumbar space.

The gross appearance of the fluids obtained by the three practically simultaneous punctures was strikingly different, indicating, as had the difference in pressure, that a double block existed. One obstruction was in the spinal subarachnoid space, the other somewhere between the lateral ventricle and the cisterna magna. The temperature rose to 104 during the evening.

June 14, the general condition was much better. The mental responses were more normal. The child was less irritable and slept quite normally. At 1 p. m., the temperature was 99.6. A lumbar puncture was done; there was little pressure of the fluid, which was cloudy; 45 cc. was removed and 45 cc. of serum introduced by gravity. At 7 p. m., the temperature was 101.2. Ventricular, cisternal and lumbar punctures were done. The same difference as on the previous day was noted. Fifteen cubic centimeters of serum was introduced into the ventricle, 30 cc. into the cisterna and 15 cc. into the lumbar space. Cultures of the fluids from all three punctures were negative.

June 15, the patient was fairly comfortable. She talked rationally. At times, she complained of severe headache. The temperature rose to 103.8 during the night, but went down to 102.4 during the day. At 4 p. m., a triple puncture was done. The lumbar fluid was under normal pressure, and slightly less cloudy; no organisms were shown on smear. A culture later showed growth. The cisterna fluid was cloudy, with less pressure than before; there were no organisms on smear or culture. The ventricular fluid was under moderate increase of pressure, slightly cloudy, and showed no organisms on smear or culture. Fifteen cubic centimeters of serum was given into the ventricle, 20 cc. into the cisterna and 45 cc. by the lumbar route.

June 16, the general condition was much improved. The child was rational, but complained of headache, stiff neck and backache. The highest temperature during the day was 103. A triple puncture was done. The 40 cc. of lumbar fluid removed was only slightly cloudy, with no pressure; 30 cc. of slightly cloudy cisterna fluid was present after the withdrawal of the lumbar fluid, but with low pressure. The 30 cc. of ventricular fluid withdrawn was slightly cloudy, with normal pressure. Thirty cubic centimeters of serum was introduced by gravity into the right ventricle; none appeared in the cisternal needle. Twenty cubic centimeters of serum was then introduced into the cisterna magna and 30 cc. by the lumbar route. All fluids were negative on smear and culture.

June 17, the condition remained the same. The temperature dropped during the day to 99. A lumbar puncture was done, with easy withdrawal of 60 cc. of cloudy fluid; 45 cc. of serum was injected. There was very slight growth on culture.

June 18, the patient was perfectly rational; she was still restless and talkative, but slept well. The temperature rose to 103.2, after dropping to 99. A lumbar puncture was done, with the withdrawal of 60 cc. of slightly cloudy fluid; 45 cc. of serum was injected. Cultures and a smear of the fluid were negative.

June 19, the temperature had not risen above 100.6. The neck and back were still stiff. A lumbar puncture was done; 45 cc. of slightly cloudy fluid under normal pressure was removed. No serum was given. The mental condition was normal. The child had the best day since entering the hospital.

June 20, cultures of the fluid removed the previous day were negative. The patient was bright, laughing and talking. The temperature had reached normal.

June 22, she was bright, but complained of pain in the head and both legs. A lumbar puncture gave nearly clear colorless fluid under normal pressure; 45 cc. was withdrawn. The smear and culture were negative. Only a slight elevation in temperature occurred.

Recovery was rapid. The stiffness of the neck and spine persisted for several days longer. Headache and pain in the back and legs did not recur. The patient had had incontinence of both urine and feces, but this difficulty quickly cleared up with the return of normal mentality.

A total of 560 cc. of antimeningococcus serum was introduced by eighteen lumbar punctures, 155 cc. by six cisterna magna punctures and 75 cc. by four ventricular punctures, making a total of 790 cc. of serum required. None of the antimeningococcus serums on the market agglutinated the organisms in this case, but the serum used killed all organisms in cultures. The fact that the serum was not absolutely specific for the particular strain of meningococcus involved may account for the unusually large amount of serum used. All injections were made by gravity. The technic used was that described by Ayer.[1]

A spinal subarachnoid block was evident after the fourth day and persisted to the tenth day. Ventricular block was present by the sixth and persisted until the ninth day.

The child had no remembrance of the first two weeks in the hospital and did not recognize her parents when her mind at first appeared clear. She returned to school in a short time and showed no mental retardation. There has been no headache or vision disturbance and no check in growth. Now, two years and seven months later, she is apparently perfectly normal physically and mentally.

CONCLUSIONS

The treatment of meningococcus meningitis by the lumbar route alone has given satisfactory results only in the presence of the most favorable conditions—early diagnosis, specific serum and low or moderate virulence of the organisms. Many patients discharged as cured are found on follow-up examination to have hydrocephalus indicating a cisternal, ventricular or cortical subarachnoid block, which had not been recognized and therefore not treated.

Puncture of the cisterna magna is indicated in all cases not showing satisfactory progress. The technic is not difficult, but should be thoroughly mastered on the cadaver before application to the living subject.

Antimeningococcus serum introduced by cisterna puncture reaches the basilar cisterna and cerebral subarachnoid spaces in greatest concentration, whereas, serum introduced by lumbar puncture barely reaches the cisterna magna.

Cisterna puncture, therefore, promises the maximum distribution with the maximum concentration in the regions first involved.

Block of the spinal subarachnoid space may be prevented by early cisterna puncture. The presence of such a block makes this procedure imperative.

Ventricular puncture, either through the anterior fontanel or in older children through a trephine opening, has proved a valuable means of treating meningococcus meningitis. It is demanded in cases showing ventricular block.

Cisterna or ventricular puncture or both combined, with the introduction of curative serum into the basilar cisterna or ventricles, will do much toward preventing subsequent hydrocephalus. In advanced or fulminating cases, these procedures may be the means of saving life.

ALBUMINURIA IN CHILDREN *

JOSEPH K. CALVIN, M.D.
BERTHA L. ISAACS
AND
JACOB MEYER, M.D.
CHICAGO

The significance of albumin in the urine of apparently healthy children is still the subject of much discussion. Most of these cases are accidentally discovered in the routine examination of urine in schools, orphan asylums and dispensaries Bright,[1] in 1827, regarded albumin in the urine as definite evidence of kidney disease. This view was held until Ultzmann,[2] in 1870, suggested the possibility of this urinary finding without an accompanying nephritis, and Leube,[3] in 1877, proved that albumin is found in the urine of many apparently healthy people. Various theories have been advanced to account for this benign albuminuria. Hooker[4] reviews the voluminous literature up to 1910. Post and Thomas[5] and Lauener[6] have summarized it up to 1923.

The frequency of the condition in children varies in the reports from different observers. Capitan[7] reported the condition in 40 per cent of healthy children, Langstein[8] in 12 per cent of children over 5 years of age, *Bugge[9] in 15 per cent, and Lauener[6]* in as high as 38 per cent. Other research work concerning albuminuria in children may especially be found in articles by Risselade,[10] Fischel and Popper,[11] Stumpke,[12] Jehle, Weith, Scholder and Swenson,[13] Faber,[14] Nassan,[15] Hamelberg,[16] and Hamill and Blackfan.[17] All of these investigators found a high percentage of albuminurias among children, especially Hamill and Blackfan, who examined 124 children whose ages ranged from 18 months to 14 years. They found an albuminuria, at some time or other, in 89 per cent of these cases

It is not our purpose in this paper to repeat the study of large groups of children to determine the incidence of albuminuria, but intensively to study small groups with the objective of throwing some light on the cause, or causes, and significance of the condition.

However, the incidence of albuminuria in 5,000 school children has been so thoroughly investigated by Lauener[6] that we feel justified in summarizing parts of his work in table 1.

TABLE 1.—*Summary of Lauener's Cases of Albuminuria in Five Thousand School Children*

Age	Number of Children	Percentage Showing Albuminuria	Percentage of Boys with Albuminuria	Percentage of Girls	Percentage Showing Trace of Albumin	Percentage Showing ++ or More
6- 7	1,246	6.7	5	8.5	5.6	0.2
10-11	1,350	27	18.6	35.5	15.6	5.7
15-16	2,481	38	29.5	46	25.5	3.2

Because of the confusion in the literature regarding the etiology of the so-called benign albuminurias, we have attempted to determine the causes by analyzing two groups of children of very different environmental and physical conditions.

One of the groups studied was composed of children having no special complaints or illnesses. They were recruited from the homes of the very poor in which hygienic conditions were at their worst, diets were improperly balanced, and teeth, tonsils and other potential foci of infection neglected. Consequently, undernourishment and anemia were common. This group will hereafter be designated as group 1.

The second group studied consisted of children living in a well regulated orphans' home under the supervision of a watchful physician. Their hygienic surroundings were very good. They lived a well regulated life with the proper balance between school work, play, recreation and rest. The meals were properly balanced. Foci of infection were eliminated as soon as discovered. Periodic physical examinations were made. This group will hereafter be known as group 2.

TABLE 2—*Data in Cases Presenting Albuminuria in Five Hundred and Twenty Children Examined (Morning Specimens Used)* *

Group	Number of Children Examined	Boys	Girls	Age Range	Average Age	Percentage of Total Showing Foci of Infection	Total Percentage of Albuminuria	Percentage Boys	Percentage Girls
1	189	103	86	2-16	8	63	60†	45	70
2	331	181	150	6-16	11	0	15	10	20

* The microscopic findings were abnormal in less than 1 per cent of the cases

† Eighty per cent of the total albuminurias (60 per cent) showed evidence of malnutrition and foci of infection

TABLE 3—*Results of Reexamination of Same Cases Over a Period of One Year*

Group	Number of Children Examined	Boys	Girls		Total Percentage of Albuminurias	Percentage Boys	Percentage Girls
2	331	151	170	6 months later	24	20	30
2	331	181	150	1 year later	15	9	22

The results of the urine examinations are shown in tables 2 and 3.

From these observations, we conclude that the incidence of albuminuria is much higher in children living under poor hygienic surroundings, having many foci of infection (untreated) and for the most part being anemic and undernourished. That these factors do play a prominent rôle in the causation of so-called benign albuminurias in children is evidenced by the fact that many respond to the treatment of these etiologic factors, as will be described later.

---

The orphanage children (group 2) have a minimum of these factors present. Lest our conclusions be misinterpreted, we wish to repeat that the findings of carious teeth, enlarged and infected tonsils and adenoids, or infected nasal sinuses merely add to the picture of a child below par physically and are not, so far as we can determine, the specific causes of the albuminuria. We feel that the correction of such defects results in an improvement of the albuminuria, mainly so far as it helps to produce a general improvement in the condition of the child.

IDIOPATHIC OR "GROWTH" ALBUMINURIA

Albumin may appear a considerable time before puberty, but it reaches its greatest incidence during adolescence, the period of greatest growth. Lauener has used the term "growth" albuminuria. He is of the opinion that growth, with its attendant phenomena, is the main factor in the albuminuria of juveniles. In his cases he found it more frequent in girls than in boys, which he attributes to their more rapid and intensive growth. We wish to direct attention to this and to point to our experiences with the orphanage children. Here are children in whom all foci of infection have been removed, who to all appearances are normal and well nourished, and whose weight curves show a definite increase; and yet, a small but fairly constant percentage manifest benign albuminuria. If Lauener's deductions are correct, it would seem that 78 per cent of the albuminurias in the orphanage children would fit into the group which he classifies as "growth" albuminurias. The remaining 22 per cent were of the orthostatic type (table 4).

The albuminuria in many of the cases studied was transitory in character, as revealed by repeated urine examinations. In group 1, on sixty-five of the 189 children studied, from two to six urinalyses were made over a period of one year. Forty of the sixty-five varied from positive to negative and back to positive or negative again. In group 2, fifty of the 331 urines examined were positive on the first examination. One week later, of the same fifty, only forty-three were positive for albumin, and six months later, only twenty-one of the original fifty albuminurias were still positive. Also sixty-two cases in which the first examination was negative showed a positive urine six months later.

ORTHOSTATIC ALBUMINURIA

Many observers have maintained or implied in their writings that the non-nephritic albuminurias found in urines on routine examinations are based on an orthostatic or postural albuminuria. Post and Thomas[5] apparently assume that the statistics of most previous authors[18] refer to the incidence of orthostatic albuminuria. Saito[19] states that 15 per cent of 148 healthy school boys from 10 to 14 years of age showed albuminuria, and that 90 per cent of the positives were of the orthostatic type. Hamill and Blackfan,[17] however, definitely imply that, although a large percentage of their cases (children) showed euglobulin in the urine, which is a fairly constant finding in orthostatic albuminuria, most of these were not orthostatic, because this amount of proteinuria was not increased by the upright posture and exercise. They found no orthostatic albuminuria in 124 cases of albuminuria that were studied. Lauener[6] states that "orthostatic and growth or 'physiological' albuminurias should have separate groupings." His statistics are concerned mostly with nonorthostatic types.

From our studies we believe that most of the so-called benign albuminurias in children are not of the orthostatic type. By orthostatic albuminuria we understand a condition in which the urine excreted while the patient is lying down is albumin free, with the subsequent appearance of it after he rises. In short, if the first specimen passed in the morning, when compared with a specimen obtained later in the day after normal activities, contains as much albumin or more, then the condition does not belong in the category of the orthostatic albuminuria.

Table 4—*Comparison of Morning and Afternoon Urine in Cases in Which the Afternoon Specimen Had Been Found Positive*

Total Number of Cases in Which Afternoon Specimen Had Been Found Positive	Total Percentage of Orthostatic Patients Among the 32 Albuminurias (in the 249 Children)	Percentage of Orthostatic Patients Among the Total Number of Children (249) Examined	Percentage of the 12* Boys Negative in the Morning and ++ or More in Afternoon	Percentage of the Total Boys (138) Examined Negative in the Morning and ++ or More in the Afternoon	Percentage of the 20* Girls Negative in the Morning and ++ or More in the Afternoon	Percentage of the Total Girls (111) Examined Negative in the Morning and ++ or More in the Afternoon
32 Boys 12* Girls 20*	7, or 22%	7, or 2.8%	4, or 33%	4, or 2.9%	3, or 15%	3, or 2.7%

We examined the afternoon urine specimens in group 2. In those found positive, the first specimen passed in the morning (night urine) and an afternoon specimen were reexamined. The results are summarized in tables 4 and 5.

Table 5—*Data of Albuminuria in Afternoon (Late Afternoon Specimens)*

Total Number of Cases	Percentage of Total Positive in Afternoon	Percentage of Total Boys (138) Positive in Afternoon	Percentage of Total Girls (111) Positive in Afternoon
249 Boys 138 Girls 111	32, or 12.8%	12, or 8.2%	20, or 18.9%

We believe our results indicate that the greater percentage of albuminurias in children are not the postural or orthostatic type. We admit, however, that at times it is difficult to differentiate between a so-called growth albuminuria and an orthostatic albuminuria, especially as one may merge into the other; but we feel that postural relationship is the most definite constant characteristic of the orthostatic albuminuria. Whereas some would assign a greater proportion of benign albuminurias to the orthostatic variety, we are more inclined to separate this group and to add that the greater proportion of benign albuminurias in children are due to the asthenia and anemia resulting from foci of infection and to growth disturbances.

---

[18] Those given in footnotes 7 to 17.

[19] Saito, H.: Clinical Investigations on Orthostatic Albuminuria, Am. J. Dis. Child. 22: 338-401 (Oct.) 1921.

ALKALIZATION

Post and Thomas[5] maintain that "every case of orthostatic albuminuria, with very rare exceptions, will become and remain albumin free, regardless of posture, exertion, time of day, or urinary concentration, as long as the urine remains neutral or slightly alkaline." Those cases which failed to respond were suspected of being the result of renal pathologic change. Nassan[20] observed similar results. Hamill and Blackfan[17] state that the reaction of the urine has no influence on the production of albumin.

Our results in ten cases studied agree mainly with the latter authors. An alkaline urine apparently did not cause the albumin to disappear, although in a few cases the amount of albumin was somewhat lessened.

TYPE OF PROTEIN

Until the recent work of Welker, it was generally agreed that the protein in the urine might be identified as either serum albumin or serum globulin, also referred to as euglobulin, or a combination of the two. Langstein[21] and Wallis[22] concluded that the protein precipitated by acetic acid added to cold urine was euglobulin, while Pollitzer[23] believed that the precipitate was caused by a combination of serum albumin and chondroitin-sulphuric acid. The precipitate is often referred to as the acetic acid body. Welker's[24] investigations disclose, however, that chemical tests for the identification of the types of protein in urine are difficult of application and interpretation, but that the precipitin test accurately identifies most of them. By means of the precipitin test, he found that the protein in urine may be identified as coagulable protein not precipitated in the cold by acetic acid (serum albumin, pseudoglobulin); or coagulable protein precipitated in the cold by acetic acid (euglobulin); or noncoagulable protein precipitated in the cold by acetic acid (mucin, nucleoprotein), and noncoagulable protein not precipitated by acetic acid at all (proteoses). There is no simple test for separating euglobulin, mucin and nucleoprotein available. All of these are precipitated in the cold by acetic acid. Hamill and Blackfan[17] especially investigated the type of protein found in the so-called albuminuria cases in children. Wallis and the latter authors believe that euglobulin is the protein mainly present in non-nephritic cases (leaky kidneys). The latter investigators noted that, in these benign albuminurias, the euglobulin was present three times as frequently as serum albumin. As these authors used only the chemical test and not the precipitin test, they of course included mucin and nucleoprotein as well as euglobulin in what they termed "euglobulin."

A simple test for albumin in the urine was used throughout our work. This test is the one commonly employed in the routine examination of urine in physicians' offices and laboratories. The technic is as follows:

> A test tube is filled about two-thirds full with clear urine. The upper portion of the urine is heated to boiling in the flame, and from 5 to 6 drops of 5 per cent acetic acid is added. The contents of the tube are viewed against a black background, and only those urines which exhibit no cloudiness are considered normal. In testing for euglobulin, the acetic acid is added to the cold urine. The urine is not heated at any time during the test for euglobulin.

The results of our investigations of the types of protein present as determined by the "cold" and "heat" acetic tests are given in table 6.

We concluded from these results that 26 per cent of the urines examined and 58 per cent of those showing a positive protein reaction contained either euglobulin, nucleo-albumin, mucin, or all of them, which precipitate out when acetic acid is added to the cold urine. As 26 per cent of the total were more positive in the hot urine, it is reasonable to assume that, at least in this number, serum albumin or pseudoglobulin, or both were present, and that in at least 18 per cent they alone were present, as this percentage reacted only in the heated urine. In two thirds of the analyses, the heat and cold test agreed (either positive or negative). In this series, 46 per cent of the total gave a positive protein reaction.

It appears from these results that either euglobulin, nucleo-albumin and mucin, or all, are prominent components of the protein in the urine in the benign albuminuria cases, but that serum albumin or pseudoglobulin may occur alone, even in benign albuminurias. Only by further investigations by means of the precipitin test can it be determined which one of the three proteins, euglobulin, nucleo-albumin or mucin, predominates in these benign albuminurias.

Table 6—*Results of Investigations of Types of Protein*

Total number of urines analyzed	906
Total number giving a positive protein test on the addition of acetic acid to the cold urine	248, or 27.4%
Total number giving a positive protein test on the addition of acetic acid to the heated urine	398, or 43.9%
Total number agreeing in both the cold and heated specimen (either positive or negative)	646, or 71.3%
Total number more positive in the heated than in the cold	238, or 26.3%
Total number more positive in the cold than in the heated	20, or 2.2%
Total number positive in the cold only	18, or 1.99%
Total number positive in the hot only	163, or 18%

COMMENT

All previous investigators agree that albuminuria is a frequent occurrence in children, especially in those over 6 years of age, becoming more frequent toward puberty. Most agree that the incidence is higher in girls. Globulinuria is generally accepted as a type of proteinuria that predominates, or is a prominent feature in these cases. Some authors maintain that most of these juvenile forms of albuminuria are of the orthostatic or postural type. Others contend that the majority are not of this type but nevertheless are harmless and of not as much importance as is customarily attached to them. Many cases have been followed into adult life and have shown no higher incidence of nephritis. It is generally agreed that the growing kidney may physiologically secrete albumin in the urine, and consequently during the period of most rapid growth (puberty) the greatest incidence occurs.

As a result of our studies, we believe that some of these albuminurias may be considered physiologic or growth albuminurias, but that many other etiologic factors may be present, which, when removed, result in the permanent disappearance of the condition. One of us has conducted an albuminuria clinic for several years for the purpose of finding the cause and eliminating it if possible in these cases. Foci of infection, especially chronically infected tonsils, adenoids, nasal sinusitis and abscessed teeth, are the chief offenders. Many cases of albuminuria have responded when treatment was directed toward these foci. Again,

undernourishment and anemia often were associated with albuminuria, which responded to the overcoming of these factors. We reiterate that we do not believe that all of these factors (foci, etc.) have any direct specific effect on the kidney. They probably are a part of the picture associated with malnutrition or an under par condition with faulty blood volume and blood flow, resulting in hypofunction or impaired function of the body tissues. In short, the albuminuria is merely one symptom of a general systemic disturbance in these cases.

We wish to direct the attention of the physician to the dangerous practice of stressing the term albuminuria too greatly to the parent or to the patient. The harm done psychically may be worse than the condition physically. Albumin in the urine is a dreaded occurrence among the laity, and albuminuria neurotics can easily be created. The "disease" often occurs only in the physician's test tube and in the mind of the patient. However, the physician must not totally disregard these simple benign albuminurias. A functional albuminuria should be regarded much as a functional heart murmur. Every case should be under the control or observation of the physician for a variable period, certainly during the period of adolescence, and for a short period following.

We offer the following classification for the convenience of the practicing physician, thus doing away with a host of misleading terms:

Benign Albuminuria.

(*a*) Malnutrition albuminuria, frequently associated with anemia, underweight and systolic basal murmur. Foci of infection, especially infected tonsils, adenoids, nasal sinuses and carious teeth, are common causes of this malnourished condition

(*b*) Orthostatic albuminuria, associated with posture.

(*c*) Idiopathic or "growth" albuminuria, including the terms juvenile, puberty, cyclic, transitory and intermittent.

According to our experience, the simplest methods of treatment should be followed. We would recommend first an intelligent explanation of the nature of the findings to the parent, explaining the simplicity and benignancy, and that it does not comprise a sickness or disease. The physician will often find that his problem is one of treating an intense, overanxious, hypochondriac parent rather than the child. Those cases which demand correction and elimination of apparent foci of infection certainly should have these done. Nutrition should be improved and anemia overcome. But we do not advise any excessive rest cure or restricted low protein diet as a remedy. Such measures may actually result in harm to children who are physically under par. The child should be allowed to lead a normal life with only such restrictions as are necessary to overcome any malnutrition; otherwise, freedom in every regard has proved to be the best remedy. Especial emphasis should be laid on the physical development of the orthostatic group.

Circulatory Changes in Anesthesia.—Chloroform is a poison to living cells, acting perhaps on the fatty surface film which controls permeability and adsorption. On the heart it causes dilatation and weak action, and under certain conditions fibrillar contraction, the cause of sudden syncope and death. . . . Chloroform, by poisoning the tissue cells and relaxing their tone, makes the whole body flabby, turns the circulation from a vigorous one through confined channels in a taut body to a sluggish one in a relaxed body, and the blood in consequence stagnates in dependent parts—hypostatic congestion. —Hill, Leonard: *Brit. M. J.*, April 24, 1926.

RECOGNITION AND MANAGEMENT OF THE CARDIOVASCULAR SURGICAL RISK *

ALFRED E. PHELPS, M.D.
Associate Attending Anesthetist, New York Polyclinic Hospital; Director of Anesthesia, Gouverneur Hospital; Anesthetist, Memorial Hospital
NEW YORK

There are few subjects in medicine in which an accurate knowledge is more urgently required than a patient's general fitness for undergoing an operation. It is well known that a major operation throws a great strain on the cardiovascular system; occasionally, this strain costs the patient his life.

Cardiac chart, with findings.

A fatal termination for this type of patient clearly indicates that the gravity of the condition of the cardiovascular system was unrecognized. An accurate appraisal of the system might reasonably correct this unsatisfactory state of affairs. It seems that the anesthetist, by virtue of the unique opportunity he has for studying the conditions of the surgical patients before, during and after operations, occupies a strategic position for gaining information that of necessity cannot be obtained by the surgeon or the internist. It was decided to undertake the investigation of this subject and to learn, if possible, to appraise the cardiovascular system with sufficient accuracy to predict the fate of a patient about to undergo an operation. It was realized from the beginning that the acquisition of this type of knowledge, in which prognosis is the object, is a process of slow growth and results only from the accurate registration and correct evaluation of a large number of single instances of phenomena and associated phenomena. However, an extended study of this nature should yield results that will be valuable.

---

* From the Department of Anesthesia of St. Bartholomew's Hospital.

That the study possess any degree of accuracy, it was necessary to supplement the work in anesthesia by attending cardiac clinics, and after several years of preliminary study, the work was begun. The accompanying chart was devised to insure uniformity in examination of the patients and for the purpose of permanent record. Owing to the fact that the majority of examinations are made immediately preceding the administration of the anesthesia, brevity and simplicity were required in the chart. In the first half of the chart, subjective symptoms are recorded for the reason so strongly emphasized by Mackenzie; namely, that they are the first manifestations of cardiovascular impairment. The physical examination is next recorded. As a rule this examination consumes only a few minutes. If, however, there is evidence of the presence of valvular, myocardial or vascular disease, the subjective symptoms and objective signs receive consideration in proportion to their gravity. In questionable risks the examination takes place, when possible, the day preceding the operation. The degree of heart failure, if any, is next considered. Then the cardiovascular diagnosis is made. We are now prepared to make a tentative appraisal of the patient's cardiovascular system. The heading entitled "Risk" is reserved for this purpose. A risk qualified "good" registers my belief that the patient's cardiovascular system will successfully withstand the strain of the operation, while "poor" indicates that it will not. The condition of the patient during and immediately after the operation, and the employment of any supporting measures, are also recorded. The postoperative course and the condition of the patient at discharge from the hospital complete the record.

In attempting a prognosis, the nature of the operation and the management of the patient before, during and after the operation must be considered. Adequate supporting measures may enable an impaired cardiovascular system successfully to withstand the strain of an operation, whereas without this support, progressive circulatory failure would be inevitable. In the designation of poor risks, the supporting measures are, in large part, discounted. That is to say, even though supporting measures are employed, the strain of the operation will be too great for the cardiovascular system. These supporting measures will be discussed in the latter part of the paper. Again, the duration of the operation is a factor bearing on the prognosis that is of the utmost importance. In this class of patients the rapidity with which the surgery is performed determines, to a large extent, its efficacy. The necessity of rapidity in these poor surgical risks cannot be too strongly emphasized. A patient of this type may withstand great surgical trauma for a short period, whereas prolonged trauma may kill him. The more surgery one sees, the more is one impressed by this fact. Therefore, in attempting a prognosis, the element of time is a vital factor.

During the past year, three patients were brought to the operating room overdigitalized. One of these cases was incorrectly diagnosed as a structural heart block. With this involvement of the conduction system and the likelihood of more extensive ventricular impairment, together with a moderate restriction of the cardiac field of response to effort by dyspnea, the patient was appraised as a poor risk (case 14). A gastro-enterostomy was performed. His condition at the end of the operation was such that a gastric resection was considered inadvisable. Recovery from the gastro-enterostomy was uneventful. This experience indicates the necessity of investigating the digitalization of patients before attempting to interpret one's findings. In patients with regular rhythm, therapeutic digitalization is of questionable value and overdigitalization possibly harmful.

Unfortunately, in this study it was not possible to make use of electrocardiograms, essential adjuncts in the appraisal of the cardiovascular system. Pardee[1] says: "The electrocardiogram has its own special variety of information; namely, the mechanism and character of the contraction of the muscle fibers of the heart. An examination of the heart is as incomplete without the electrocardiogram as it is without auscultation or a determination of the size of the heart. By omitting any of these methods, we may deprive our-

selves of information of considerable value in the diagnosis. . . . If the patient has the retrosternal pain coming on with exertion and relieved by rest, typical of disease of the coronary arteries, or has had a severe typical attack of angina pectoris, it is very common to find significant abnormalities of the ventricular wave. About 70 per cent of those patients will show one or more of the abnormalities mentioned, even though the heart is quite normal in size and free from murmurs; half of these have the special T wave peculiarity associated with coronary narrowing. . . . Of these patients who have cardiac enlargement and symptoms of circulatory insufficiency, the number showing abnormal electrocardiograms will be quite large. These have the diffuse myocardial degeneration from arterial narrowing or from multiple foci of low-grade infection within the muscle; and abnormal ventricular waves are found in about 85 per cent. They are often referred to as having 'cardiosclerosis.'"

There is presented, in the accompanying tables, a series of cardiovascular appraisals assembled from the past year. The series includes only patients of 50 years of age and over on whom major operations were performed. No patient is included who was a poor risk as a result of a surgical condition; this excludes a large number of patients. Despite their paucity, analysis discloses a number of interesting facts.

All patients without symptoms or without signs referable to the cardiovascular system and therefore appraised as good risks, and all patients with mild symptoms and signs of circulatory insufficiency and therefore appraised as probably good risks, proved to be good risks.

Eight patients were appraised as poor risks. Of the men, three died; on two, operations were curtailed because of poor condition, and one did well. Of the women, two did well; no operations were curtailed and no patients died. Women seem better subjects than men. Subjective symptoms and objective signs in men referable to the cardiovascular system indicate an impairment of that system of a more serious nature than do the same symptoms and signs in women.

Anginal symptoms in women were mild, inconstant and secondary. One man (case 9) with syphilitic aortitis, moderately restricted in effort by retrosternal pain, did well. One man (case 16), markedly restricted in effort by retrosternal pain, died suddenly on the nineteenth day after operation, after a smooth and uneventful convalescence. Two men (cases 10 and 21), each moderately restricted in effort by dyspnea, without pain, with moderately enlarged hearts, marked diminution of intensity of the heart sounds, reduplication of the first apical sound, and subnormal blood pressures, died, one on the fourth day and the other on the fourteenth day.

Two patients developed, on the day following their operations, auricular fibrillation, which lasted two days and four days, respectively, on digitalis medication.

REPORT OF CASES

Case 16.—A banker, aged 63, with markedly limited response to effort, had retrosternal pain after five minutes' walking on the level, pain which came on when he walked against the wind, climbed a flight of stairs and on grades; he could not hurry. The pain did not radiate. There were no sensations of constriction of the chest and no exhaustion. For the past year pain always occurred on slight exertion, relieved by rest. Gas and urination were common during the attacks. The symptoms were progressive.

The patient was well nourished; the heart was enlarged, the left border almost to the anterior axillary line; the sounds were diminished in intensity at the apex and almost inaudible at the base, with a systolic blow at the apex; the rhythm was regular; the radials were thickened. The systolic blood pressure was 137; diastolic, 78. Because the patient's surgical condition was considered critical, a cholecystotomy was performed, in spite of his marked cardiac impairment. He had a smooth, uneventful convalescence. On the morning of the nineteenth day after operation, having finished breakfast, the patient stated that he never felt better; a few minutes later he complained of a queer feeling and suddenly died. No postmortem was obtained.

Sudden deaths are common in angina pectoris, but this patient did not die during an attack. In fact, he had been quite free from anginal pain for about a month, because he had been confined to bed. The exact mechanism of his death is unknown. In what degree the operation, nineteen days before, was contributory to his death is also a matter of conjecture. In dealing with such conditions, we are confronted by aspects of reality as yet beyond our powers of registration.

Case 10.—A traveling salesman, aged 66, somewhat overnourished, but who had lost 40 pounds (18 Kg.), had a response to effort moderately limited by dyspnea, which had been more marked during the past year. The heart was moderately enlarged; the sounds showed a marked diminution of the intensity, with reduplication of the first apical beat, but no murmurs; the rhythm was regular and the radials thickened. The systolic blood pressure was 116; diastolic, 76. The red blood cells numbered 3,980,000; the white cells, 7,500; the hemoglobin was 75 per cent. The blood chemical findings were normal. An excision of a carcinoma of the rectum, by the abdominoperineal route with colostomy, was done; the operation lasted one and one-half hours; a hypodermoclysis of physiologic sodium chloride solution was given during operation. Transfusion of 500 cc. of whole blood was done immediately after the operation, though the patient's condition was considered fairly good. Immediately after the operation and before transfusion the red blood cells numbered 3,800,000; the white blood cells, 12,000; hemoglobin, 78 per cent. I saw the patient four hours after the operation; the volume of the pulse was good, but not as good as it should have been, considering the transfusion; the patient slept under scopolamine-morphine anesthesia. Convalescence was smooth and uneventful up to the seventh day after operation. After a very restful night, at 7 a. m., he became suddenly dyspneic, and cold and clammy; the pulse was scarcely perceptible, and the heart sounds were muffled, though there was no pain; a half hour later he became unconscious and remained so for about half an hour. The internist diagnosed the attack as probably due to occlusion of a small coronary artery. After a few hours, the patient was more or less completely recovered, and the pulse and general condition apparently good again. He had several similar attacks on successive days, some of which followed colonic irrigations. On the twelfth postoperative day, there were signs of pneumonia at the right lower base. On the fourteenth day, the patient died. No postmortem was obtained.

It will be noted that this patient had an uneventful convalescence up to the seventh day following the operation. The exact cause and nature of his subsequent repeated attacks are unknown. The repetitions strongly implicate the heart as the offending organ. The strain of the operation was too great for the cardiovascular system. Transfusion was done immediately after the operation; less strain on the impaired heart would have been entailed had the patient been fortified by an additional transfusion before the operation, but his general appearance had been misleading. Whether the latter transfusion would have prevented the fatal termination is problematic, but it is believed that it would have done so.

Deaths of this nature are frequently classed as cardiovascular "accidents." It is believed, however, that such cases possess symptoms and signs which, appraised before the operation, will indicate the advisability or inadvisability of an operation.

SUPPORTING MEASURES IN CARDIOVASCULAR SURGERY

Success with the poor surgical risk depends in a large measure on the judicious management of this type of patient before, during and after opeartion. The advisability of transfusion before the operation is determined by the condition of the patient and the nature of the operation. A patient with a poor cardiovascular system, facing a long, severe operation, should have a transfusion done before the operation, even though there is little or no anemia present. The best results are obtained when the transfusion immediately precedes the operation. Transfusion after the operation in many of the poorer risks may also be necessary; an immediate transfusion is advised if the patient's condition is unsatisfactory. Treatment should begin before circulatory failure is at all pronounced.

Transfusion is the most effective method we possess to prevent and combat circulatory failure incident to surgical shock. Physiologists are practically agreed that the chief cause of circulatory failure in shock is the reduced volume of blood returned to the heart. The vascular system, to function properly, must contain at all times an adequate supply of fluid, and the best fluid is whole blood. The force of ventricular contraction is determined by the diastolic volume previous to contraction, provided marked changes in arterial resistance or alterations in inherent contractility of the heart are not produced.[2] Transfusion aids materially in maintaining a normal diastolic volume through adequate venous return and likewise prevents marked changes in arterial resistance. In the poor risks under consideration, it possibly minimizes any tendency, due to surgical shock, to alterations in inherent contractility.

A hypodermoclysis of physiologic sodium chloride solution sustains and prolongs the good effects of a transfusion given immediately before the operation; and when there is no preliminary transfusion, hypodermoclysis is even more urgently required.

It is also helpful with these patients to substitute a combination narcotic in place of the general anesthesia during the latter part of the operation. In the case of a laparotomy, such as gastric resection, the general anesthesia is continued with as low a level maintenance as possible until the resection begins. At this time morphine, from 1/6 to 1/4 grain (10 to 16 mg.), scopolamine, 1/200 grain (0.3 mg.) and atropine, 1/150 grain (0.4 mg.) are administered hypodermically. Five minutes later, the general anesthesia is discontinued and the operation completed, as a rule, without additional anesthesia. As a consequence, the strength of the patient is conserved.

Another essential in the management of the poor risk is absolute rest after the operation. The urgency of this is often not fully appreciated. Any exertion whatever immediately following a prolonged and severe operation on a patient with cardiac impairment may prove fatal. The return of consciousness in practically all patients is accompanied by movements of the arms and legs, at times sufficient to require moderate restraint. This exertion on the part of the patient may be prevented by administering hypodermically, fifteen or twenty minutes before the close of the operation, the medication mentioned in the previous paragraph. The patient passes into a deep sleep that lasts from four to six hours. Even transfusion after the operation fails to awaken him. Absolute rest is assured. This method has been frequently used during a number of years, with only favorable results. To continue the complete rest into the following day, one or two additional doses of morphine is all that is required in most instances.

Changing the position of the patient during the operation should be arranged, when possible, to occur in the beginning rather than at the end. For example, in an excision of the rectum for carcinoma by combined abdominal and perineal routes, it is well to begin with the perineal operation, in order that the change of position may occur early, when the patient is in relatively good condition.

Again, in transporting a patient from the operating room to the bed, no effort should be spared to give the least possible disturbance to him. These minor details are of the utmost importance to those of poor physical condition undergoing severe operations. Conservation of strength is a vital necessity.

SUMMARY AND CONCLUSIONS

1. All the patients without symptoms and without signs of cardiovascular impairment withstood the strain of a major operation.

2. All the patients with mild symptoms and signs of cardiovascular impairment also withstood the strain of a major operation.

3. Of six men with advanced symptoms and signs of cardiovascular impairment, three died; of two, operations were curtailed; one did well.

4. Two women with advanced symptoms and signs of cardiovascular impairment did well.

5. Transfusion of whole blood is the most effective method to prevent and combat surgical shock.

6. The hazard to patients with cardiovascular impairment undergoing long, severe operations is minimized by transfusion immediately before and after operation.

7. Complete mental and physical rest is insured by morphine, from 1/6 to 1/4 grain (10 to 16 mg.), scopolamine, 1/200 to 1/150 grain (0.3 to 0.4 mg.), atropine 1/150 grain, given before the patient leaves the operating room.

TUMORS OF THE CAUDA EQUINA

REPORT OF TWO CASES

JULIAN M. WOLFSOHN, M.D.
AND
EDMUND J. MORRISSEY, M.D.
SAN FRANCISCO

It is all too true that the diagnosis of tumors of the cauda equina has been made notoriously late in the course of the disease.

One who looks over the literature on this subject is struck by the fact that most of these patients have been treated for long periods for disturbances other than that from which they were suffering. The most common erroneous diagnoses include sciatica, rheumatism, gallbladder disease, appendicitis, neuritis, Pott's disease (case 1 in our series), lumbago and sacro-iliac disease (case 2).

Spiller and Frazier[1] found in their cases that the average duration of the disease before correct diagnosis was made was two and three-fifths years. Two of Cushing's[2] cases were "of many years' duration." Elsberg[3] reported a case of one and one-half years, while Hamill's[4] patient suffered for ten years before the correct diagnosis was made and proved.

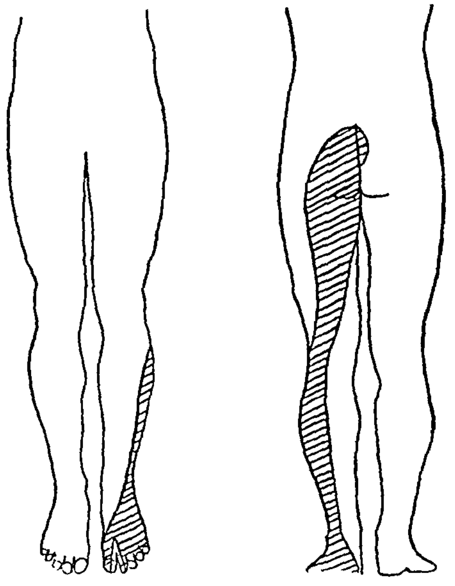

Fig 1 (case 1) —Front and back views of area affected by cauda equina tumor, in which there is loss of sensation to light, touch, pain and temperature (indicated by shading).

The apparent explanation of this delay between the onset and final correct diagnosis is that the symptoms and signs presented in the majority of these cases are obscure and indefinite. The usual case of caudal disease passes through a more or less rapid acute phase into a stage either intermittent, as regards symptoms, or chronic. Therefore, on the basis of their symptomatology, the localization of caudal lesions is not always easy, as, for instance, we see in contrast in the acute inflammatory or traumatic caudal lesions in which the clinical picture is clearcut. The taking of a careful history and frequent examinations for insignificant or evanescent physical signs might lead to early suspicion of caudal involvement.

The symptomatology of the acute caudal lesion is of the same type as that found in the chronic long-standing case. It might be well to refer here briefly to the work of Roussy and Lhermitte,[5] who have so clearly systematized caudal lesions after trauma. These writers say:

> The syndromes by which one interprets injuries of the roots or the nerves of the cauda equina manifest themselves in various ways, according to the height of the lesion, its extent or its depth, as is easily understood in view of the anatomic details presented above. Nevertheless, there is an entire series of signs common to the lesions of the cauda equina that serve to individualize them.[6]

They have divided the traumatic cases (and this really includes the acute nontraumatic case) into five main syndromes, each with its own symptomatology and clinical findings:

> 1. The total type syndrome, corresponding to high lesions beginning at the level of the second lumbar vertebra.
> 2. Middle type (lumbosacral) syndromes, corresponding to lesions in the region of the lumbosacral articulation (from the fifth lumbar to the first sacral vertebra).
> 3. The lower type syndrome, corresponding to lesions purely sacral.
> 4. The hemicaudal syndrome, in lesions affecting only half of the cauda.
> 5. The root type syndrome, in which few or many roots of the cauda are involved In this type a few of the lumbosacral roots are attacked alone or haphazard. The reader is referred to Roussy's succinct description of the foregoing syndromes.

One realizes that classifications as described above are inadequate, because syndromes in chronic cases only approximate those found in acute cases. Nevertheless, bearing this in mind, the interpretation of subjective and objective findings will suggest early caudal involvement of one of these types in most cases.

Once our suspicion is directed to the cauda, it is necessarily important to determine other data about the lesion. To do this, several methods of approach have been advocated.

Roentgen-ray examinations of the lumbosacral region and lumbar puncture in the early cases are usually negative.

Cushing and Ayer,[2] Mestrezat,[7] Spiller and Frazier,[1] Guillain[8] and many others have obtained below the lesions in later cases a yellow (xanthochromic) spinal fluid, poor in cellular content and rich in protein (Froin's syndrome). This type of fluid has always been considered indicative of a more or less complete spinal block above the site of puncture. Recently, however, Cushing and Ayer discovered that xanthochromia of less intensity also exists above the level of the lesion in some of their cases, as in case 1 of the present series. Thus, simple lumbar puncture has little localizing value.

A procedure of value in some cases is that used by Ayer and Mixter,[9] who established the presence of a spinal block by combined cistern-lumbar puncture. This procedure, like that of Queckenstadt, in itself has little localizing value.

[9] Ayer, J B, and Mixter, W. J.: Radiography Following the Injection of Iodipin into the Spinal Subarachnoid Space, Arch Neurol. & Psychiat. 11: 499 (April) 1924.

Certain French authors have found that, during lumbar puncture, even though the block is incomplete, injection of air in like amount for the spinal fluid withdrawn will produce root pains at the level of the lesion. We have no experience with this method.

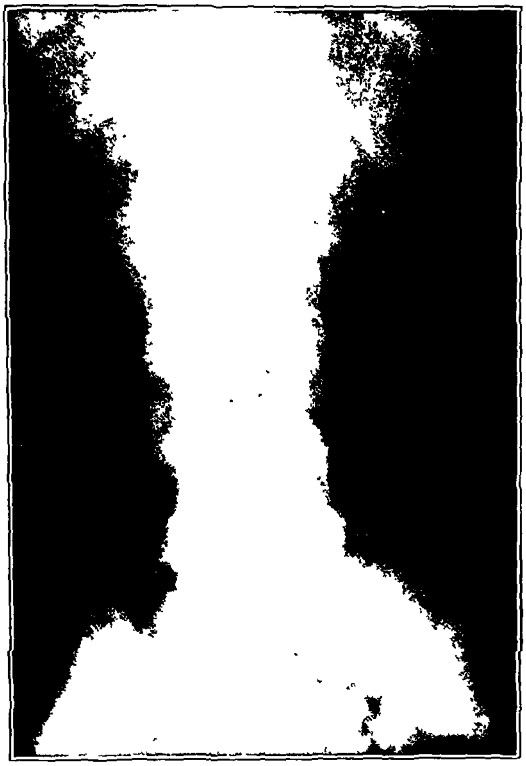

Fig. 2 (case 1).—Complete block of lower border of third lumbar vertebra, anteroposterior view.

After all, the most valuable accessory for accurately localizing spinal block lies in the introduction of from 2 to 3 cc. of lipiodol (iodized oil) into the cisterna magna by Sicard's[10] method. With the patient in a sitting posture, the oil rapidly passes into the spinal subarachnoid space and is checked at the level of the block, which can then be beautifully visualized by roentgen-ray examination with the patient in the erect posture (figs. 1 and 2).

During the last few months the two cases of caudal lesion described below have been diagnosed, and the patients operated on in the Stanford service of the San Francisco Hospital. These cases are of sufficient interest, we feel, to report, as they exemplify most of the foregoing comments.

REPORT OF CASES

Case 1.—F. B., an unmarried man, aged 27, entered the Stanford surgical service of the San Francisco Hospital, Dec. 28, 1925, complaining of an ulcer of the heel of the left foot. The familial and past history were essentially negative. The present illness began fifteen years previously, at the age of 12, when he was struck in the lumbar region with a baseball, following which he experienced rather sharp pains in the back, radiating down both legs. These pains would come on in the evening after he had played all day, but very little attention was paid to this complaint until about one year later, when it was noticed that he was getting "bow-legged." He then consulted a physician, who placed him on a Bradford frame for eight months with the diagnosis of Pott's disease. Then he was up in a wheel chair for several months, and for the following two years he walked with the aid of crutches, at the end of which time he was able to discard them. On being removed from the frame the patient noticed that the left leg was smaller than the right. Sensory changes began about two years after the accident, and when we saw him sensation was absent over the left buttocks, the posterior part of the thigh, and the outer surface of the left leg and foot. The patient felt that sensory loss had remained stationary for several years. Seven years previously, he had a resection of the left cuneiform, with a transplantation of the extensor hallucis longus to the cuboid.

He entered the hospital for an ulcer of the left heel received, October 1, about two months previously, when he rested his anesthetic foot on the exhaust pipe of a machine, sustaining a severe burn.

The patient was well developed and nourished. The general physical examination was negative. The neurologic examination showed the head and the cranial nerves and lobes of the brain normal. The upper extremities were normal. In the lower extremities, there was slight atrophy associated with weakness of both legs from the knees down, more marked on the left side; flexion and extension of the left ankle were limited; pronation and supination were practically absent on the left; extension of the great toe was absent on account of the tendon being cut. There was no paralysis, rigidity or contractures. There was absent sensation to pain, touch and temperature over the left buttock, the posterior part of the thigh and the outer surface of the leg and foot. Deep muscle sense and vibratory sensation were normal; i. e., the fourth and fifth lumbar and the first, second and third left sacral segments were affected (fig. 1). The rectal sphincter tone was poor. Muscular reflexes were: radial, biceps and triceps, present and equal; abdominals, present; cremasterics, absent; patellars, equal and slightly hyperactive; Achilles, absent on both sides; Oppenheim, Gordon and Babinski, absent. The lateral view of the roentgenogram of the lumbar and sacral vertebrae showed the disk between the fourth and fifth lumbar

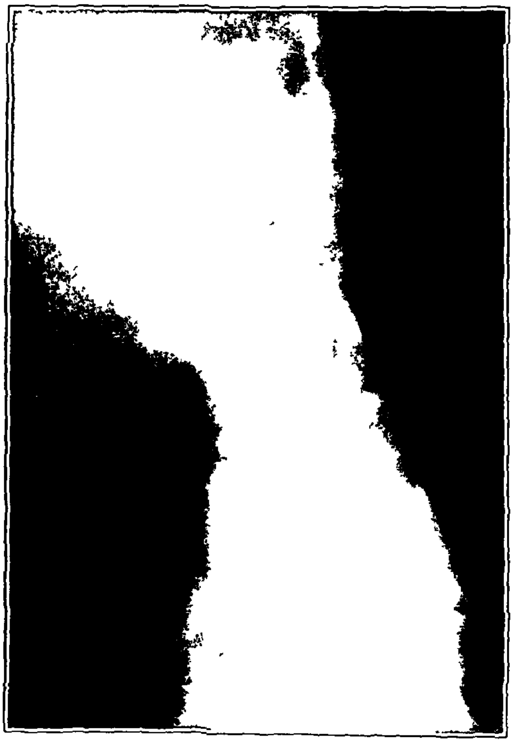

Fig. 3 (case 1).—Lateral view showing lobulation of obstruction.

---

10. Sicard, J. A.: Rev. neurol. 4: 1264, 1921.

vertebrae intact. The articulation facets were obscured. There was a cystlike absorption of the posterior half of the bodies of the fourth and fifth lumbar vertebrae, as if from pressure rather than from a destructive new growth. The laminae were thin and hazy.

The blood Wassermann reaction was negative. Blood examination showed: hemoglobin, 90 per cent; leukocytes, 11,900; polymorphonuclears, 72 per cent; small lymphocytes, 24 per cent, and large lymphocytes, 4 per cent.

Spinal fluid could not be obtained by spinal puncture, but a cisternal puncture showed the fluid clear and colorless. No cells were present and the globulin was negative. The urine was normal.

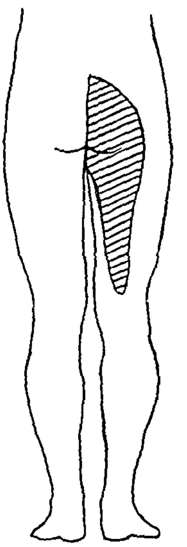

Fig 4 (case 2) — Back view of area affected by cauda equina tumor, in which there is loss of sensation to light, touch, pain and temperature.

Three cubic centimeters of lipiodol was injected following the cisternal puncture, and roentgenograms taken one hour, twenty-four hours, and forty-eight hours later showed that the lipiodol remained at the level of the lower border of the third lumbar vertebra, a small streak extending slightly lower on the left (figs. 2 and 3). The conclusion was: obstruction at the level of the third lumbar vertebra.

Laminectomy revealed a large solid tumor filling most of the spinal canal and lying dorsal to the fourth and fifth lumbar vertebrae. Section of the tumor showed it to be fibroma. Convalescence was uneventful, and the patient was discharged, Feb. 28, 1926.

Case 2.—G. S., a Greek waiter, aged 34, unmarried, entered the San Francisco Hospital, Nov. 25, 1925, in the Stanford surgical service, complaining of constipation and pain in the left lower abdominal quadrant and the buttocks. The familial history was negative; the past history was negative, except for a gonorrheal infection.

The present illness began about three and a half years previously, with dull aching pain in the lumbar region, occasionally radiating down both legs to the ankles; the pain was present only at night, waking the patient from a rather sound sleep, and would then increase in severity until he arose in the morning, when it would disappear during the day. After the first six months, pain was present both day and night, and had been slowly increasing in severity, more marked on the right side. At the onset, he complained of a burning pain in the perineum. During the last two and a half years, he had been suffering from rather marked constipation, requiring a laxative every evening. For the last six months he had had polyuria, with occasional periods in which he suffered from dysuria and slight incontinence. There was no impotence. Various diagnoses were made during this period, varying from sacro-iliac disease to colitis.

The patient was fairly well developed, but poorly nourished. General examination revealed a spastic contracted descending colon and gonococci on urethral smear.

Neurologic examination of the head, cranial nerves and the lobes of the brain was negative. In the upper and lower extremities, no paralysis, weakness, atrophies, hypertrophies, rigidity or contractures were present. Sensation to touch, pain and temperature over the right buttock and the posterior part of the thigh was absent; i. e., the areas supplied by the first, second and third sacral segments (fig. 4). There was no loss of deep muscle sense. Vibratory sensation was normal.

Muscular reflexes were: radial, biceps and triceps, present and equal; abdominals and cremasterics, present; patellas, present and equal; Achilles left, absent; right, present on reinforcement.

Roentgenograms of the lumbar and sacral spine showed that the sacrum had six segments. The lateral masses of the first segment had not united perfectly. There were hypertrophic fringes on some of the lumbar vertebrae. The lateral view of the lumbosacral articulation showed no evidence of spondylolisthesis. The top of the sacrum made an angle of 50 degrees with the fifth lumbar vertebra. On account of the lumbar lordosis, this made a weakness at this joint. There was a slight list of the spine to the right. The left pubis was slightly higher than the right. These findings suggested that there was a sacro-iliac slip.

The blood Wassermann reaction was negative. Slightly yellow spinal fluid, obtained by cisternal puncture, the spinal puncture being unsuccessful, gave: a negative Wassermann reaction; Noguchi reaction, plus; Nonne-Apelt, minus; Pandy, plus plus and a colloidal gold curve of 1111222200. The urine was normal. Nov. 4, 1925, about 3 cc. of lipiodol was injected, following a cisternal puncture, and a roentgenogram made later showed a complete block at the level of the third lumbar vertebra (figs. 4 and 5).

Laminectomy was done in two stages on account of the troublesome bleeding encountered. At the first operation, the laminae of the third, fourth and fifth lumbar vertebrae were removed. A very vascular tumor, the size of a cherry, was uncovered to the right of the cord at the level of the foramina between the fourth and fifth lumbar vertebrae. On removal of the posterior surface of the first and second sacral vertebrae, which was very thin, a mere bony shell, a cyst the size of a large walnut, which contained a clear, deep golden yellow fluid, was opened up. The nerve roots were seen running through the cyst. On account of the bleeding, it was thought advisable to do the operation in two stages. At the second operation the dura was opened and the tumor, an angioma, was approached from below, but uncontrollable bleeding was again encountered. Attempt at removing it had to be postponed. The patient is now receiving deep roentgen-ray therapy. Spinal fluid withdrawn above the tumor at the time of the second operation was quite yellow.

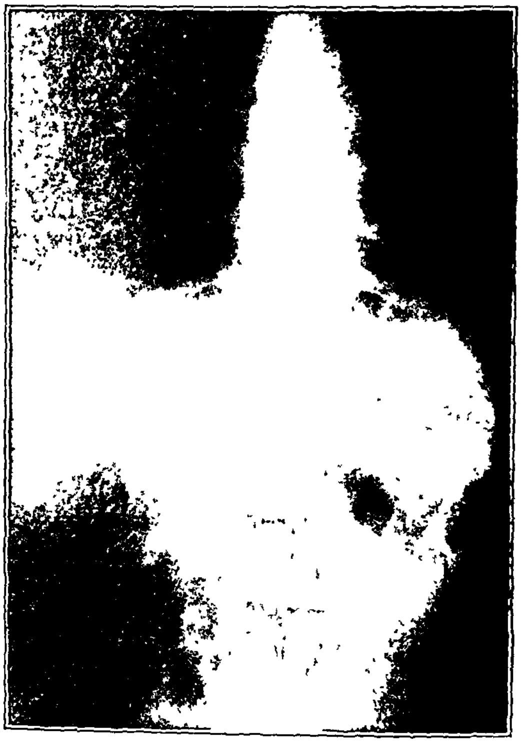

Fig. 5 (case 2).—Injected lipiodol arrested at level of third lumbar veretebra.

COMMENT

These two cases of cauda equina tumors are illustrations of delayed and incorrect early diagnosis.

Patient 1, treated for Pott's disease, suffered for thirteen years before a correct diagnosis was made. His subjective symptoms, most of this time, pointed to caudal disease, and future diagnoses were most probably colored by the previous erroneous diagnosis.

Patient 2 presented a suggestive caudal lesion: burning pains in the perineum, radiating pains, increased by recumbent posture and relieved by walking, and severe constipation, which was absent before the present illness. This is a suggestive and important triad of caudal symptoms, which our patient presented for about two and one-half years. Two of these symptoms were present three and one-half years.

1. Both patients presented few positive neurologic findings.

2. The diagnosis of caudal lesion was made preoperatively in each case and confirmed by the intrathecal use of lipiodol, which accurately localized the upper level of the lesion.

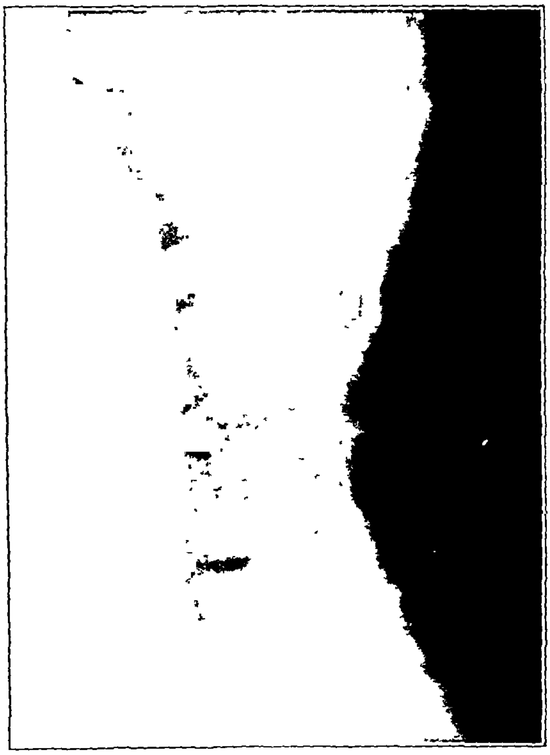

Fig. 6 (case 2).—Lateral view.

3. Both these cases conformed, in a general way, to type 2 (middle type syndrome of Roussy and Lhermitte).

4. In case 2, xanthochromic spinal fluid was found below the tumor at operation, and above the tumor even as high as the cisterna magna. This confirms the discovery of Cushing and Ayer.

5. In our cases, Queckenstadt's and Ayer's tests could not be performed, because of the presence of the tumor in the lower lumbar region which prevented lumbar puncture.

CONCLUSIONS

1. Lesions of the cauda equina are more common than supposed.

2. If one keeps in mind the possibility of caudal lesion as the cause of symptoms, systematic examination will result in earlier correct diagnosis in these cases.

3. Lipiodol injected intrathecally has been found by us to be innocuous. It was a valuable adjunct in these cases, not only in confirming the diagnosis, but, what is more important, in localizing the level of the lesion.

ROENTGENOGRAPHY AND THERAPY WITH IODIZED OILS*

W. T. BELFIELD, M.D.
AND
H. C. ROLNICK, M.D.
CHICAGO

Two proprietary iodine-oil compounds, lipiodol and iodipin, extensively used in recent years for roentgenography and therapy, are now known to produce two harmful effects which restrict their usefulness: first, because, virtually nonabsorbable, they may remain in the tissues for indefinite periods, for two years in one instance: and, second, they may cause by prolonged contact irritation and cicatrix formation.[1]

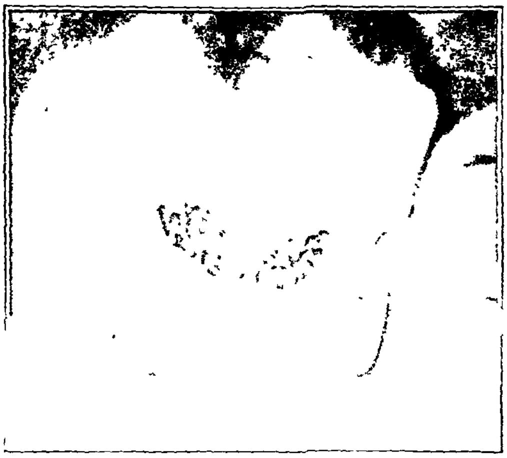

Fig. 1—Normal vasa and vesicles filled with iodized oil through vasotomy; the vesicle fills before the fluid passes out through the ejaculatory duct, this we have observed through the fluoroscope also. Hence the vesicle must be considered a reservoir for spermatozoa.

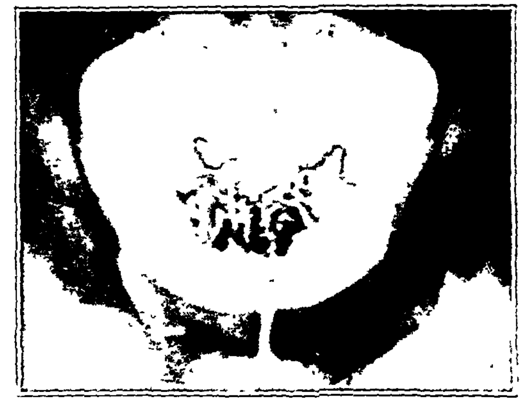

Fig. 2—Both vasa redundant, kinked and uniting into a single ampulla; both vesicles filled by vasotomy without escape of oil into ejaculatory ducts.

We have studied the therapeutic effects of these and other iodized oils after injection into the seminal ducts through vasotomy, usually bilateral, in sixty-seven men, with immediate roentgenograms in all; the viscosity of lipiodol and iodipin renders the filling of the vesicles difficult and at times incomplete (fig. 3). The failure of absorption, observed by others in various tissues, is shown in the persistence of lipiodol in the vesicles and in the connective tissue at the internal inguinal ring (Bogros' space), into which it was intentionally injected by way of the sheath of the scrotal vas (fig. 5).

Iodipin and lipiodol are said by their respective makers to contain unnamed iodine compounds in vegetable oils. Since animal oils are more readily absorbed,[2] we have dissolved iodine and various of its compounds in each of several animal oils and have injected these into the vesicles. Our prime object was therapeutic efficacy with harmlessness, which properties we have found in several solutions, notably two:

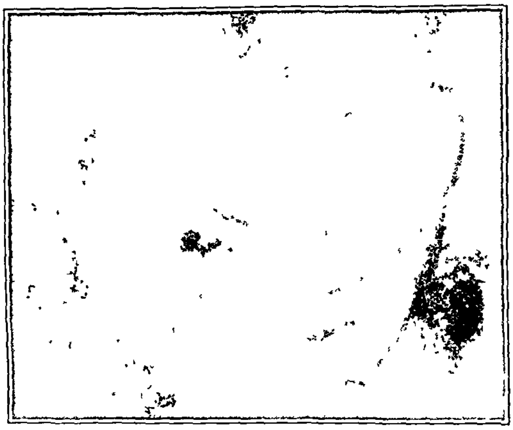

Fig 3—Right, silver wire passed into vas through vasotomy, arrested by kink in vas, left, vas and vesicle incompletely filled.

Iodol, 10 Gm., in cod liver oil, 40 cc. Of this, iodine constitutes more than 18 per cent by weight.

Thymol iodide, 10 Gm, in 30 cc. of cod liver oil. The iodine content of this is about 12 per cent. Either solution is prepared by stirring together the two ingredients.

Either liquid clears the vesicles of gonococci and of the pyogenic bacteria commonly found in them. They are sufficiently fluid to fill the vesicles without undue pressure. They are absorbable and do not produce cicatrix formation. Hence their use nullifies the only criticism of vasotomy; namely, the possible occlusion of the vas at the site of injection through perivasal cicatrix formation. We now frequently use iodized oil for vasotomy instead of collargol solutions.

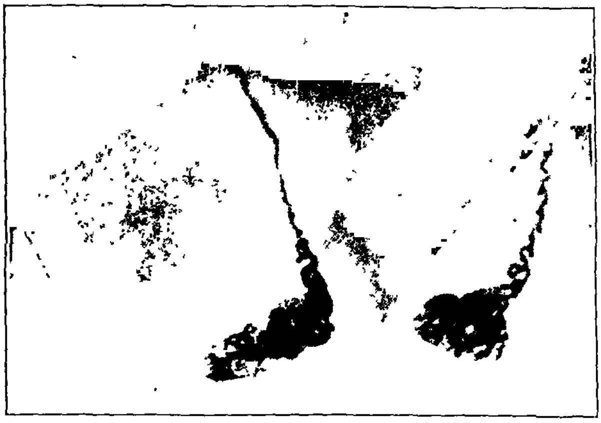

Fig. 4.—Iodized oil forcibly injected downward in living subject through vasotomy fails to pass beyond the tail of the epididymis; no pain during injection nor irritation afterward.

It is known that disease conditions of the deep urethra, such as chronic infection or stricture, may be accompanied with such atony of the ejaculatory ducts as to permit the entrance of the urine into the vesicles during urination;[3] there sometimes results the constant presence in the vesicles of urinary salts, including triple phosphate crystals and urates. We have in such cases injected from the meatus into the bladder medicaments which the patient then voids while the urethra is compressed. For this method of treating the deep urethra and vesicles, the iodized oils are especially adapted; for should they pass from vesicle into vas—which Rolnick[4] has shown seldom happens—they go no farther than the tail of the epididymis, where they produce neither present pain nor subsequent irritation (fig. 4).

The iodol-oil mixture gives a fair roentgenographic shadow of the vesicles (fig. 1), less dense than that furnished by the customary collargol 10 per cent solution, or by lipiodol. We have not used it elsewhere; but since roentgenograms of the vesicles are unusually elusive—for example, a 20 per cent solution of sodium iodide or a 10 per cent solution of sodium tetraiodophenolphthalein, injected into the vesicles gives no distinct shadow—it is possible that these iodized oils may be found useful in other fields as harmless and inexpensive substitutes for lipiodol and iodipin.

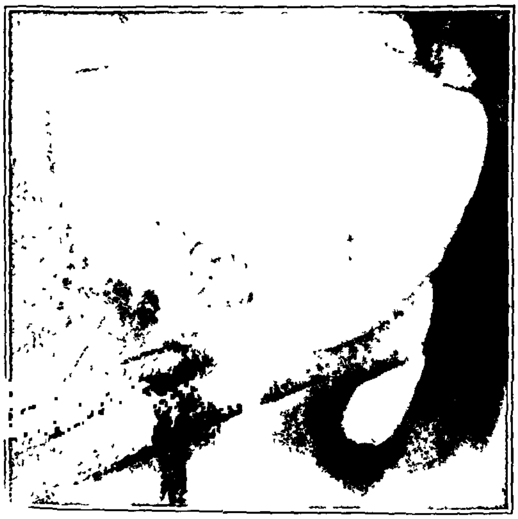

Fig. 5—Persistence of lipiodol in Bogros' space (*A*) and vesicles thirty-seven days after injection; the oil injected toward the body within the sheath of the scrotal vas diffused through Bogros' space but did not enter sheath of pelvic vas.

INDUSTRIAL HERNIA

Attention is called to the clinical importance of Bogros' space, especially to industrial surgeons. The sheath of the intrapelvic vas is usually not continuous with the sheath of the scrotal vas.[5] Each segment ends in the intervening loose connective tissue at the internal inguinal ring, Bogros' space (fig. 5); hence infections traversing the sheath of the vas from the vesicles diffuse into this space, causing tender swellings, even suppuration, at the internal ring, which simulate hernia. Although a description of such imitation hernias incidental to pelvic infections was published a half century ago by Hutchinson,[6] and by others[7] subsequently, it has received scant attention from surgeons or urologists. Yet the need for this knowledge is now more urgent than ever before because of recent legislation requiring compensation for industrial injuries, which has produced a large crop of pseudo "industrial hernias." Many of these have been recognized by urologists as infections that have traversed the vas to Bogros' space from the vesicles; and many such industrial hernias have been cured by treatment of the infected vesicles.[8] Wesson,[9] as consultant in industrial insurance, personally observed in two years forty-seven instances in which traumatic hernia had been diagnosed, and in many of which herniotomy had been advised. In only one was hernia found; in all there was a tender swelling about the internal inguinal ring, and in all there was pus in the vesicles. Treatment of these infected organs abolished the pseudohernia in many instances.

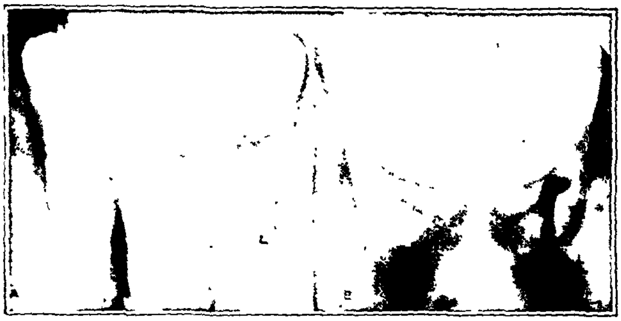

Fig. 6.—*A*, lipiodol injected into sheath of left vas; iodol in cod liver oil into sheath of right vas; *B*, same field twenty-one days later: lipiodol unabsorbed, iodol in oil nearly all absorbed.

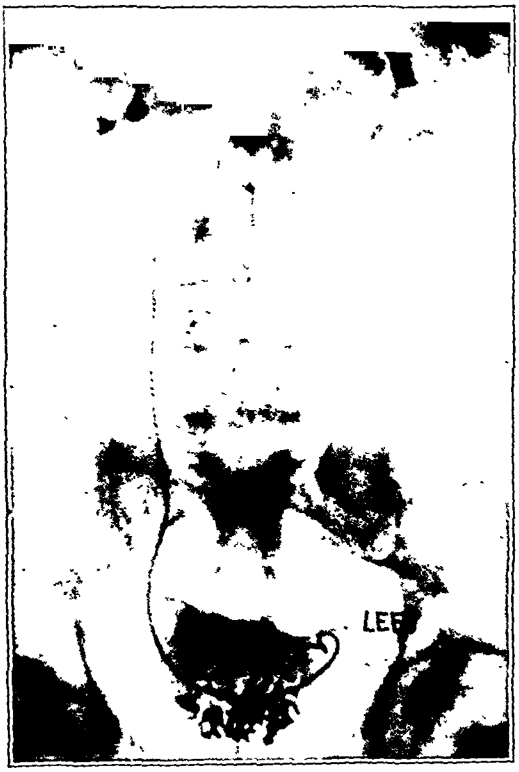

Fig. 7.—Relation of vasa and vesicles (filled with iodized oil) to ureters; catheter in right ureter; sodium iodide, 15 per cent, in left ureter and pelvis.

For many surgeons and physicians, the seminal vesicles do not exist; thus in the Manual of Periodic Examinations recently issued by the American Medical Association they are not named, though the prostate is recognized as a possible seat of infection. Obviously, the industrial surgeon cannot safely ignore the seminal vesicles, because of their relation to industrial hernia, so called.

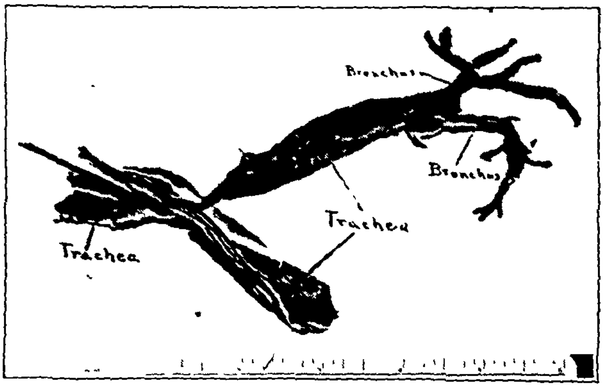
DIPHTHERITIC CAST OF BRONCHIAL TREE*

Perry A. Bly, M.D., Rochester, N. Y.

A woman, aged 34, was admitted to the Rochester Municipal Hospital on the sixth or seventh day of illness with a clinical diagnosis of laryngeal diphtheria.



Diphtheritic cast of bronchial tree.

Soon after her arrival, she coughed out a large piece of membrane which proved to be a cast of the trachea, both bronchi, and several bronchioles. Membrane also extended from the anterior nares to the nasopharynx. Antitoxin had not been given. Cultures were positive for Klebs-Loeffler bacilli. Death occurred twenty-four hours later.

MANEUVER TO FACILITATE PASSAGE OF CATHETER THROUGH A MARKEDLY TORTUOUS URETER FOR SECURING ROENTGENOGRAMS

Bransford Lewis, M D, and Grayson Carroll, M D,
St. Louis

A recent experience was interesting and valuable for developing a maneuver that paved the way to the passage of a ureteral catheter up a ureter that at first proved impassable both to the catheter and to the fluid introduced for roentgenography.

Mrs. W. B, aged 71, was extremely weak and decrepit, and it was highly desirable to make a definite diagnosis of the renal condition. At cystoscopy, January 19, on the left, the catheter passed readily, but on the right side it was obstructed within an inch of the lower orifice Several different sizes and kinds of catheter were used successively, but nothing could be made to go farther than the one inch Holding this in place as best we could, 12 per cent sodium iodide solution was injected and a roentgenogram taken which gave us a at least to the situation, as shown in figure 1. The kidney evidently was down in the *pelvis leading to tortuosity* and angulation of the ureter to such a degree that it could not be threaded with the catheter; and the catheter was obstructed so low down in the ureter that the fluid could not be made to go through the full length of the channel. It occurred to us that if we could elevate the pelvis of the patient, and manipulate and push upward into the abdomen the involved right kidney, it might straighten out the ureter enough to permit the transit through it of the catheter. This was tried out, January 22, and it proved successful. While the kidney was maintained at as high a level as possible, the ureteral catheter was gradually pushed upward, meeting with, but by successive manipulations passing, the several angulations *shown in both figures* 1 and 2, and finally reaching the neighborhood of the kidney pelvis; after which the sodium iodide solution was successfully injected and a good roentgen-ray demonstration was attained. This showed a pyonephrotic kidney on the right side situated almost within the pelvis, and a tortuous and angulated ureter throughout.

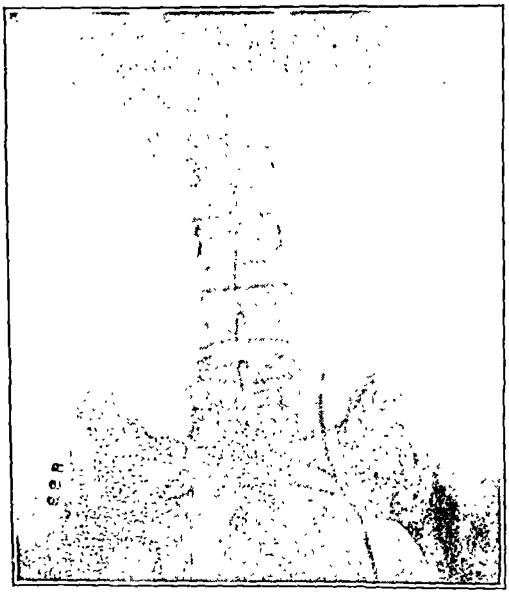

Fig. 1.—Marked tortuosity and sharp angulation of right ureter, preventing the passage of a catheter and permitting only partial injection for a ureterogram, with no pyelogram evident.

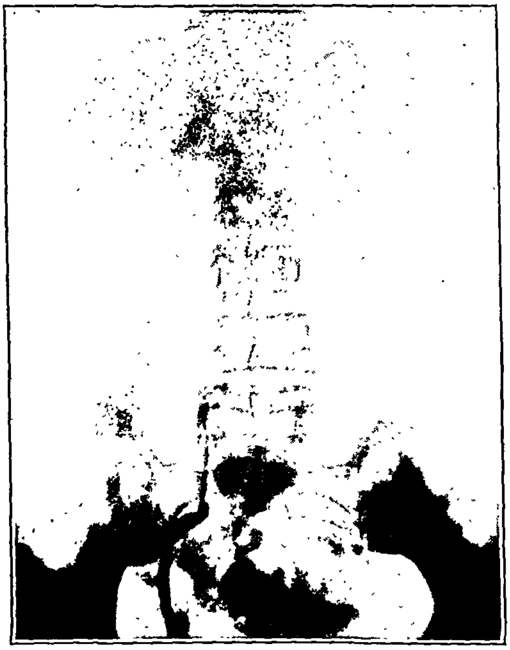

Fig. 2.—The right ureter, less kinked and tortuous, permits the ascent of the catheter (which is seen within the ureter). Ureterogram and pyelogram (*A*) show size and course of ureter and location of dilated kidney pelvis.

The lesson to be deduced from this case is the success of straightening out the ureteral channel by the maneuver described for the purpose of permitting the passage of the ureteral catheter for either diagnostic or therapeutic purposes.

550 Century Building.

DEFORMITY OF THE AIR BUBBLE OF THE STOMACH IN CARCINOMA *

Jacob Buckstein, M.D., New York
Consultant in Gastro-Enterology, U. S. Veterans' Bureau; Associate Roentgenologist, in Charge of Gastro-Intestinal Roentgenology, Bellevue Hospital; Lecturer in Gastro-Enterology, New York Polyclinic Medical School and Hospital

In a fluoroscopic survey of the abdomen, an important factor that may be overlooked is the appearance of the magenblase, or air bubble of the stomach. The normal air bubble (fig. 1) has a wide variation as to size and shape, but all agree in the absence of any irregularity in contour. By a careful inspection of this region, irregularities due to the projection within it of an infiltrative mass may be noted, and a diagnosis of carcinoma of this region made, even prior to the administration of a barium meal. The barium, however, by coating the mass, may bring it into clearer relief.

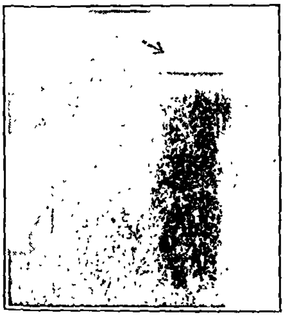

Fig. 1.—Appearance of normal air bubble of stomach, indicated by arrow.

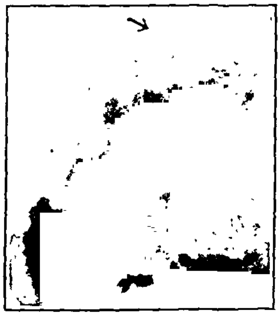

Fig. 2.—Deformity due to projection within bubble of a mass, making the base convex.

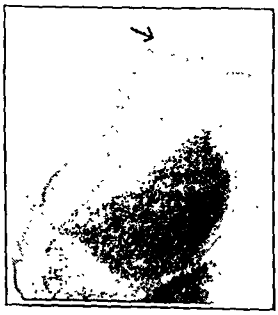

Fig. 3.—Deformity due to projection of irregular mass; base of bubble irregular.

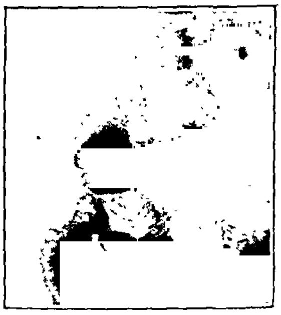

Fig. 4.—Extreme deformity, almost total disappearance, of bubble, because of an irregular infiltrative mass.

In order to emphasize the *significance of the deformed* bubble, I am including the roentgenograms of three cases of operatively demonstrated carcinoma of the cardiac zone of the stomach. These cases represent various degrees in deformity, from the crescentic deformity of the base, due to the invading mass, as noted in figure 2, to the almost total obliteration of this region, noted in figure 4.

1 West Eighty-Fifth Street.

A CORNEAL SHIELD*

Alfred W. Adson, M.D., and Albert A. Schroeder,
Rochester, Minn.

Following division of the sensory root of the gasserian ganglion for the relief of trigeminal neuralgia, a subsequent anesthesia remains over the skin, the cornea and the conjunctiva supplied by the trigeminal nerve. This anesthesia is a sequela that the patient must accept in lieu of the excruciating pain that is associated with the disease. The anesthesia is not of any particular significance except in the cornea, where it allows the entrance of foreign bodies into the eye and the consequent abrasion of the cornea without the patient's knowledge. Injuries of this kind are extremely serious, since postoperative corneal ulcers heal slowly and often fail to respond to the usual treatment; they may result even in serious opacities of the cornea and finally in loss of vision. Hence, it is highly imperative that the patient protect the cornea, on the side operated on. For this purpose, a special corneal shield has been devised.

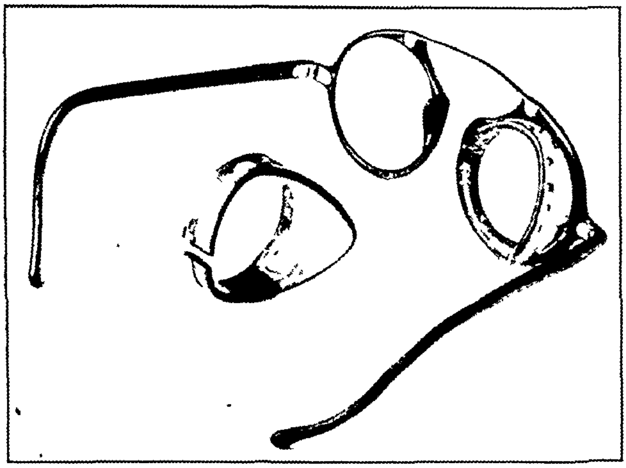

Fig. 1.—Eye cup of the corneal shield, which is constructed of zylonite and may be molded or ground to fit any orbit; a metal band holds the lenses securely in place; the cup is 42 mm. in diameter, and will fit any standard 42 mm. frame.

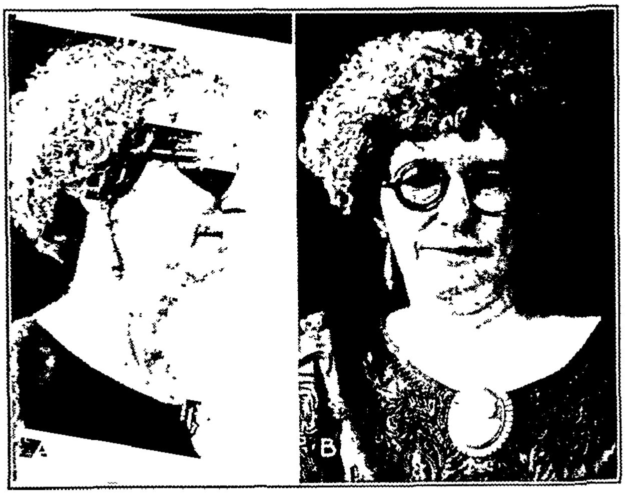

Fig. 2.—*A*, Lateral view of corneal shield and frame. The cup is fitted to a specially constructed frame. This type of frame is recommended, since it fits more satisfactorily than the saddle-bridge frame, and can be worn with greater comfort; *B*, corneal shield in place in frame adjusted to a patient who previously had an operation for trigeminal neuralgia.

The corneal shield possesses the merit of excellent protection to the cornea, and can be made to fit any substantial frame. It can be ground or molded to fit any orbit, and carries any lens that may be required for refractive errors. It is made of crystal and zylonite, is more or less inconspicuous, and is light enough to avoid pressure on the cheek. Therefore, it is ideal for patients who have been subjected to the operation on the gasserian ganglion or division of a sensory root; it may also be used for glasses for persons who wish protection for the eye against the entrance of foreign bodies.

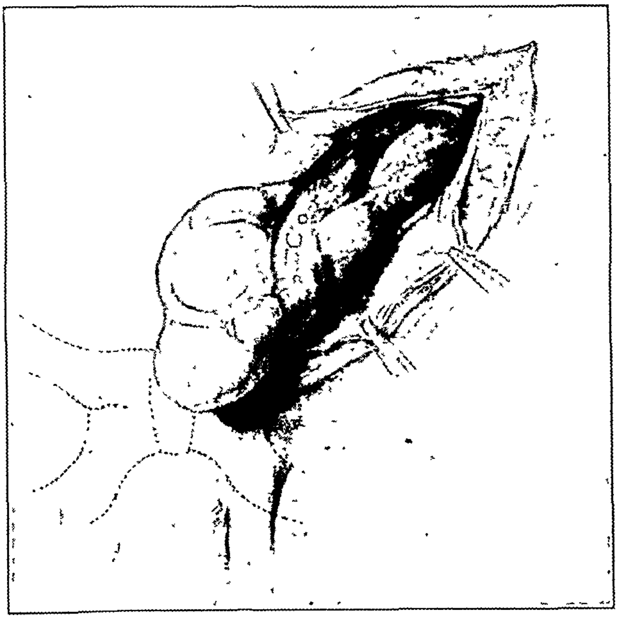
PARAFFIN IN SAC OF INGUINAL HERNIA*

Edmund Andrews, M.D., Chicago

P. C., a man, aged 49, entered the hospital with the diagnosis of inguinal hernia. He was not a suitable subject for surgery on account of advanced arteriorenal disease. However, in the right groin was an irregular mass measuring about 5 by 12 cm. It was largest at its medial end, where it lay anterior to the pubis. At the lower end it was freely movable but seemed to enter the inguinal canal, where it tapered off and was lost in the deeper structures at the level of the internal ring. It was sharply defined, lobulated, not in the least tender to touch, and caused no discomfort. It did not give any impulse on coughing or straining. Gradual firm pressure could mold this mass into varying shapes.



Hernial sac distended with paraffin; cord in groove in mass; sac entirely free from surrounding structures.

The patient said that fourteen years before he had had a hernia on the right side and that some physician had injected it with paraffin causing this lump. Since then he had had no difficulty whatever. It was felt, therefore, that there was a very real danger of malignant changes and that the paraffin should be removed.

When the canal was opened, I was surprised to find that there were no adhesions. The needle had evidently entered the empty hernial sac and distended it. This distended sac lay exactly as free as any other hernial sac, and it was very easily freed by blunt dissection up to its neck. As shown in the illustration, the cord lay in a groove in the wax. The paraffin filled the sac up to its opening into the abdomen, and it was with considerable difficulty that I could reach the empty part. The hernia was closed without any difficulty in the usual manner.

The interesting points in this case are, first, that it was possible by such means to produce a cure of a hernia which was described as being quite large. The dangers of such a procedure are evident. In the first place, one could not insert the needle into the lumen of the sac one time in twenty. If the sac had not been empty, serious complications would inevitably have resulted. Second, this foreign substance lay inert in the tissues for fourteen years without giving rise to any disturbance. Paraffin injections as a rule run a very different course. The material breaks up into small droplets, which spread through the tissues, causing enormous scar tissue production, which is exceedingly liable to malignant changes. That such was not the case here may perhaps be attributed to the fact that it lay within a synovial sac which was able to maintain its integrity and prevent these untoward sequelae.

(Continued from page 1769)

ENEMAS

Rectal injections, also known as enemas, clysters or lavements, may be large or small; either may be given high or low. An enema of less than half a liter might be considered a small enema; of more than half a liter, a large enema. When a rectal injection is given by means of a syringe with a short tip, it is deposited just within the sphincter of the anus, and is then known as a low enema. A high enema is given with a soft rubber tube (colon tube) introduced as high up in the rectum as possible, but not more than from 4 to 6 inches. The lower part of the rectum, where the short tip deposits the injection, is normally very intolerant of distention, which is responsible for the prompt evacuation of any fecal matter that arrives in this part of the bowel. For this reason, even a small enema, when given low, may cause evacuation. The upper part of the rectum, which is reached by the high enema, is more retentive as well as more absorptive.

Retention Enemas.—It is always well to precede a retention enema by a cleansing enema, so as to unload the lower bowel of fecal matter that may be contained in it, thereby lessening distention and favoring retention. After this cleansing of the lower bowel, one should wait for at least an hour before introducing the retention enema to permit the excitation caused by the evacuant enema to subside. It is furthermore desirable to make a retention enema as small in bulk as possible. A low retention enema should not be larger than 100 cc. in bulk, not more than from 30 to 60 cc., if possible; and "micro-enemas," rectal injections of very small bulk (from 15 to 30 cc.), are still better. While, other things being equal, the smaller in bulk the enema the better, to be retained, enemas must be quite devoid of irritating properties. Hence, unless the solution can be rendered unirritating within the limits of the bulk that can be retained when given low, the high technic will have to be resorted to. Thus given, less than 300 cc. can usually be retained voluntarily as long as desirable. The retention of an irritative substance may be favored by making its solution as nearly isotonic as possible, and by using colloidal fluid, such as starch water (1 per cent). If the fluid is introduced very slowly and steadily, the rectum does not become as readily aware of the distention, and retains a quantity of fluid that would otherwise be expelled. Giving the enema at the body temperature favors retention, as extremes of temperature excite peristalsis. Roentgen-ray examinations have shown that position, provided the patient is recumbent, has little to do with favoring the inflow of the enema, unless the knee-chest position is employed. The patient should be instructed to indicate by a sign—such as the raising of a finger—when he has the sensation that he could not hold any more. It is then usually best not to attempt to introduce more; and, if the quantity injected was quite insufficient for the purpose intended, to repeat the procedure in an hour or two. When the nozzle of the syringe is withdrawn, a napkin may be pressed against the anus. The patient should occupy the recumbent position for at least an hour after the injection, and should be instructed to resist any inclination to evacuation as much as possible.

The most practical apparatus for the hands of the untrained, by means of which to give such injections to infants and children, is a somewhat pear shaped soft rubber "ear syringe." One of soft rubber is better than one with a hard rubber tip, for the latter might inadvertently injure the little one, should it jerk suddenly and unexpectedly. These syringes hold about a wineglassful of fluid, which is as much as or more than should be injected at one time in an infant. During the injection, the bulb should be squeezed as slowly and gently as possible. If the syringeful is not retained, the next hour half the quantity might be introduced. The enemas are repeated at two hourly or even hourly intervals in accordance with the amount retained at each injection. In this manner 20 cc. of fluid an hour may generally be introduced into the system of infants, an income of considerable value in conditions of water starvation present or threatening, as in cases of obstinate vomiting and profuse sweating or when, because of painful deglutition or nasal obstruction, the infant does not take fluid as well as it should. Sometimes the giving of nasty medicines may so prejudice the infant—and the tendency to prejudice is the greater the lower the mentality—against any fluid administered that it even refuses food and drink. In such cases, rectal administration of food and fluid may have to be resorted to for a while. The difficulty might have been avoided altogether, if the medicine had, in the first place, been given by the bowel, which when the technic detailed above is employed, is many times easier than getting the medicine swallowed. When acidosis is either present or threatened, the addition of 2 per cent of sodium bicarbonate is probably of advantage and of 10 to 20 per cent of commercial glucose [59] ("corn syrup") still more important.

For the adult a medium sized soft rubber catheter fitted to the barrel of a glass syringe (whose piston has been removed), to serve as a funnel, is probably the safest means of administering such injections, in the hands of the untrained, as with this equipment an excess of pressure cannot be produced. A common cause of failure of retention is the use of a "fountain syringe" or similar irrigator hung so high as to deliver the fluid at so excessive a rate and pressure that it is rejected quite as fast as it is squirted in. In the adult there should be no difficulty in having 50 cc. of fluid retained every two hours, and more if necessary.

---

* This is the twenty-fourth of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

[59] It would be well if the term dextrose were employed whenever the pure d glucose, now official, is desired, and the word glucose used for the syrupy mixture on the market.

It seems that this method of intermittent introduction of fluid is superior to the once popular continuous drip method of administration, which requires the constant presence in the bowel of a tube, which becomes irksome to the patient and demands so much care and attention on the part of the attendants as to make it quite unpopular with the nurses. Nevertheless, as this method may be of value in cases in which maximal quantities of fluid are to be introduced, the following quotation from its originator, John B. Murphy,[60] who perfected it for the treatment of perforative peritonitis, will have to suffice as directions for the technic. By means of it, it is reported, as much as 30 pints of physiologic sodium chloride solution has been administered in twenty-four hours to a child 11 years old and it was all retained.

> The fluid should be administered through a fountain syringe to which is attached a three-eighths inch rubber hose fitted with a hard rubber or glass vaginal douche tip with multiple openings. This tube should be flexed almost to right angles 3 inches from its tip. A straight tube must not be used, as the tip produces pressure on the posterior wall of the rectum when the patient is in the Fowler position. The tube is inserted into the rectum to the flexion angle and secured in place by adhesive strips binding it to the side of the thigh so that it cannot come out; the rubber tubing is passed under the bedding to the head or foot of the bed, to which the fountain is attached. It should be suspended from 6 to 14 inches above the level of the buttocks and raised or lowered to just overbalance hydrostatically the intra-abdominal pressure; i. e., it must be just high enough to require from forty to sixty minutes for 1½ pints to flow in, the usual quantity given every two hours. The flow must be controlled by gravity alone and never by a forceps or constriction on the tube, so that, when the patient endeavors to void flatus or strains, the fluid can rapidly flow back into the can, otherwise it will be discharged in the bed. It is this ease of flow to and from the bowel that insures against overdistention and expulsion onto the linen. The fountain had better be a glass or graded can, so that the flow can be estimated. The temperature of the water in the fountain can be maintained at 100 degrees by encasement in hot-water bags [or by partial immersion of an electric light globe]. The fountain is refilled every two hours with 1½ to 2 pints of solution. The tube should not be removed from the rectum for two or three days. When the nurse complains that the solution is not being retained, it is certain it is not being properly given; even children tolerate proctoclysis surprisingly well.

The author believed that, next to a conservative technic of the operative procedure, proctoclysis is second in importance as a life saver in perforative peritonitis.

McClanahan[61] describes a modification of this method that he considers practically fool-proof. The apparatus consists merely of an irrigating can and a rectal tube with the end cut off. The can rests on a small table at the bedside at about the level of the patient's rectum, and care should be taken at all times that the top of the level of the fluid in the can is not more than 4 inches above the level of the rectum of the patient. The rectal tube extends from the can, under the bedclothes, into the rectum of the patient. No regulation of flow is needed, as a constant to and fro communication is maintained between the large bowel and the container at the bedside.

Nutrient Enemas.—These are employed when it is impossible or undesirable to introduce food into the stomach, or when it cannot be retained. As the colon has practically no digestive capacity, and fat is practically not absorbed from it, the use of milk, egg or meat is irrational, and to "predigest" them unnecessarily troublesome. Dextrin or dextrose, albumose-peptone, and alcohol are the nutrients to be used. As dextrose is isotonic in from 5.2 to 5.4 per cent solution, and it is better, when adding it to sodium chloride solution, to adjust the total osmotic tension to the physiologic by taking half of each, as 27 Gm. of dextrose and 4.5 Gm. of sodium chloride to 1,000 cc. of water, it will be seen that the amount of carbohydrate that can thus be introduced is rather small. Dextrin, on the other hand, is colloidal and nonirritating, while easily converted into dextrose by the ever present diastase. Hence from 10 to 15 per cent of dextrin might be employed, giving us two or three times the nutritive value of dextrose enemas. As dextrin has no osmotic pressure, the addition of salt to produce isotonicity is required. Albumose-peptone, such as Witte peptone, may be added to enemas in quantities of from 5 to 10 and even 20 per cent; and it has been shown that the presence of salt in small quantity favors its absorption. The quantity of alcohol employed should not exceed 3 per cent.

The following general rules on the administration of nutrient enemas may be of value:

Not more than three nutrient enemas should be given in the twenty-four hours, at about eight hour intervals. The amount should at first not exceed 150 cc., to be gradually increased to 300 when given as ordinary enemas, though on drop by drop instillation (Murphy technic) the quantity may reach 1 liter. After each administration the patient should keep as quiet as possible for at least two hours, and suppress any desire to evacuate the bowel. Of course, patients who need nutrient enemas are kept in bed continuously, as rest in bed lessens the consumption of calories by at least 25 per cent. To favor retention, tincture of opium may be introduced, in small doses given in a microenema about thirty minutes previously.

A cleansing enema daily is advisable. This should precede the nutrient enema by about an hour. Introducing other enemas in the intervals between the nutrients is undesirable, as it lessens the chances of retention. It is best to give the nitrogenous and the carbohydrate enemas separately. In accordance with these considerations, von Noorden[62] proposes the following formulas: Enema 1 = albumose-peptone, 60 Gm.; sodium chloride, 2.5 Gm.; alcohol, 9 cc.; water, 300 cc. Enema 2 = dextrin, 100 Gm.; sodium chloride, 2.5 Gm.; alcohol, 9 cc.; water, 300 cc. For drop by drop enemas, the concentration of the dextrin had better be reduced to 15 per cent; that of the albumose-peptone, to 10 per cent. To calculate the caloric income on the basis of the composition of such enemas is fallacious, as a certain proportion of the nutriments is undoubtedly decomposed by bacteria, and thus becomes useless to the system. Hence rectal alimentation is slow starvation; but the starvation is slower than it would be without the nutrient enemas.

THE NATURE OF GASTRO-INTESTINAL MOTILITY

Motility is one of the striking functions of the alimentary canal. The orderly propulsion of its contents is an essential response to the presence of food; when for some reason the muscular contractions of the gastro-intestinal tract become disorderly, manifestations ranging from mild distress to highly untoward effects may arise. In the genesis of both the normal and aberrant phenomena of alimentary movement, extrinsic and intrinsic nervous factors as well as the muscular tissues may be concerned. What are the respective rôles of each? On the answer to this question will depend, in no small degree, all measures of relief or promotion that are directed toward conditions of gastro-enteric motor functions.

The principal types of gastro-intestinal motility, as they have recently been summarized,[1] are peristalsis and hunger contractions in the stomach, peristalsis and rhythmic segmenting contractions in the small intestine, and peristalsis and antiperistalsis in the large intestine. Gastro-intestinal motility of all these types has been observed following section of the extrinsic nerves supplying the stomach and intestine. Consequently, it is generally assumed that this motility, though normally subject to central nervous control through the extrinsic nerves, originates in the neuromuscular mechanism in the walls of the stomach and intestine.

In attempting to ascertain whether motility of certain of these types is initiated in the enteric nervous system or in the enteric musculature, Thomas and Kuntz[1] of the St. Louis University School of Medicine have studied the consequences of administration of nicotine in doses sufficient to paralyze the most peripheral elements of the enteric nervous mechanism. They observed that the rhythmic gastric and intestinal movements persist even under these conditions; therefore the capacity to contract rhythmically seems to be an inherent property of the gastro-intestinal musculature. The St. Louis investigators have also noted that the tonus of the muscle and the amplitude of the contractions undergo frequent changes, under experimental conditions, while the enteric nervous mechanism remains functional. Such changes do not occur following complete paralysis of the enteric nervous system. The rate of the rhythmic contractions is not materially altered by conditions affecting the nervous mechanism, but is altered by conditions affecting the muscle. It is concluded that although the capacity to contract rhythmically is probably inherent in the gastro-intestinal musculature, motility of this type would be functionally inadequate in the absence of nervous control. The enteric nervous mechanism brings about variations in the tonus of the musculature and the amplitude and force of the contractions, and initiates and coordinates peristaltic and other reflex movements in response to local stimuli. Under normal conditions, these activities are subject to some degree of control by the central nervous system through the extrinsic nerves. Without the participation of nervous control, the motor activities of the alimentary canal show a mechanical regularity quite unlike the modulated and extremely variable activity that characterizes the normal viscus. Recurrent changes in the type of rhythmic activity, frequent modifications of tonus, and amplitude of contractions are the characteristics of a mechanism guided by a certain degree of nervous control that determines its unique functional responses.

SOME RECENT CONTRIBUTIONS OF CHEMISTRY TO MEDICINE

The basic sciences on which medicine is founded have assumed individual prominence at different times. Much medical research at present, if concerned with fundamentals and not with purely superficial aspects, requires the resources of chemistry. Within recent years, especially, this science has aided in many of the important advances in medicine. In his little book, "Chemistry and Recent Progress in Medicine," Dr. Julius Stieglitz of the University of Chicago discusses the modern additions to therapeutics in the field of preparative chemistry and the chemical explanations furnished for some of the bodily functions and processes.

Among the new drugs, ethylene has been exceedingly prominent. A substance long known to chemistry is suddenly shown to possess therapeutic value. New drugs for special phases of the treatment of syphilis are being proposed from time to time, usually chemical modifications of arsphenamine. Sulpharsphenamine and tryparsamide are examples of this group.

---

[1] Thomas, J. E., and Kuntz, A.: A Study of Gastro-Intestinal Motility in Relation to the Enteric Nervous System, Am. J. Physiol. 76: 606 (May) 1926.

The antiseptic properties of the aniline dyes, first discovered by Churchman[1] in 1912, when he observed that after certain gram-positive bacteria had been mixed with gentian violet they failed to grow, has, in the succeeding years, been put to therapeutic use. First employed locally, as in the lavage of joint infections, gentian violet was given intravenously in 1923 for generalized infections.[2] Mercurochrome-220 soluble is now used intravenously in septicemias and other generalized infections, and locally to the point of replacing iodine.

Besides substances foreign to the body, preparative chemistry is concerned with the isolation and preparation of products present in the normal body and necessary for health, but absent in certain disease conditions. Insulin is an example. Pituitary extract, epinephrine and thyroxin have been known longer, and the active principles of the ovary and testis remain to be identified and isolated.

While the foods that contain vitamins and the effects of their absence can be determined by purely biologic means, the real nature and properties of these elusive substances will be discovered only by chemical analysis. An important start has been made in the case of vitamin A in the work of J. C. Drummond.[3] Using the unsaponifiable fraction of cod liver oil, about 1 per cent of the total, he has separated the 10 to 15 Gm. of vitamin-containing material from 10 Kg. of the oil. Of this, only 0.005 mg. is needed daily for the normal growth of a rat. He has found that this substance contains only carbon, hydrogen and oxygen, but its exact composition remains to be determined. The chemical study of vitamin B proceeds rapidly. Two years ago, Seidell[4] prepared from brewers' yeast a crystalline picrate which has the antineuritic properties of vitamin B and for which he determined the chemical formula. W. H. Eddy[5] also obtained a highly active product from yeast, which has the relatively simple formula $C_5H_{11}O_3N$. This substance enabled growth of young rats fed on a diet lacking in vitamin B. Vitamin C has proved rather more difficult to handle, as it is readily destroyed by oxidation with atmospheric oxygen. However, Zilva[6] has succeeded in obtaining it in far more concentrated form than that in which it exists in nature, so that 0.15 mg. is a sufficient daily dose for guinea-pigs and monkeys. The discovery of the existence of the antirachitic substance now called vitamin D in the sterols of certain fats such as cod liver oil, and in cholesterol and other substances after they have been exposed to ultraviolet rays, is an important contribution to the knowledge of that prevalent condition. These excellent results tend to dispel the rather common idea that vitamins are indefinite or hypothetic "principles," instead of true chemical entities which can be subjected to ordinary laboratory manipulations and thereby purified at least to some extent.

Equally elusive are the toxins and antitoxins, but progress is being made toward their isolation and the analysis of their nature. Their relation to the proteins is being gradually worked out, and the substances for therapeutic use are being more highly concentrated and purified, with consequent reduction of untoward reactions. Indeed, the entire subject of immunology is closely related and indebted to chemistry. As Dr. H. G. Wells[7] has said: "The immunological reactions are chemical reactions. . . . The reagents involved are substances endowed with active chemical properties, and they are the product of chemical activity of the tissues of the body."

A few of the achievements of preparative chemistry have been mentioned, and there remains the contribution of chemistry toward explaining the functions and mode of action of different elements in the body. The study of calcium and phosphorus, their normal concentration in the blood and variations from the normal, and the conditions under which calcium phosphate is precipitated, have thrown much light on the problem of rickets. From purely chemical considerations, Howland[8] has set forth the conditions under which calcium phosphate is precipitated to form bone: briefly, when the product of the calcium and the inorganic phosphorus exceeds the solubility product constant for the salt at the given hydrogen ion concentration. A low carbon dioxide tension, such as exists in cartilage and other inactive tissue, favors the precipitation. In the normal child, the product is from 50 to 60; when it falls below 30, rickets is always present; between 30 and 40, rickets is usually present. He has also shown that phosphorus is the deficient element in rickets, being 3.5 mg. or below instead of the normal 5.5 to 6 mg. per hundred cubic centimeters of serum, while the calcium may be normal. One can therefore follow the improvement from an antirachitic agent not only clinically but also by chemical examination of the blood.

Clearly related to clinical medicine is the chemistry of the complex relations between blood serum and cells, and the distribution and movements of electrolytes and water between the two. One practical outcome of this study is the use of carbon dioxide as a respiratory stimulant in carbon monoxide poisoning and occasionally following anesthesia. The conditions governing the movements of salt and water between the blood and tissues are fundamental in the problem of edema, and from them a universally satisfactory explanation of this much discussed condition may sometime be evolved. Lastly, in the explanation of oxidation and reduction by modern chemistry, we have an attempt at explaining the fundamental processes of life. These reactions occurring in the body can best be studied from the nature of oxidation outside and the principles which control and limit the reaction. The subject is too complex for discussion here, but one can readily appreciate its importance and the value of understanding the processes on which all life rests.

FEDERALIZED MEDICAL TREATMENT VERSUS THE PRIVATE PRACTITIONER

By the Veterans' Act of 1924, Congress authorized hospitalization of veterans at government expense, without regard to the nature or origin of the disability. This treatment of disease at government expense was made available to all veterans in certain classes, without reference to the ability of the individual to provide treatment at his own expense or his right to obtain it from the state or city in which he lived. THE JOURNAL[1] called attention a few months ago to efforts at extension of the scope of this federal aid. May 17, the House of Representatives passed a bill[2] extending such government attentions to cover outpatient treatment as well as hospitalization, and enlarging the term "veterans" to include women who served as army nurses under contracts between April 21, 1898, and Feb. 2, 1901, contract surgeons and contract dentists. This bill is now pending in the Senate.

The government cannot be niggardly in the reward it gives for military service, but treatment and hospitalization for disabilities not incurred in the line of duty cannot be regarded as a recompense for such service. As they have no logical relation to the military or quasimilitary status of the beneficiary and are not proportioned to the military service rendered, they can be regarded only as gratuities. How long before the same reasoning that has provided these nonmilitary bounties may be expected to provide similar arrangements for governmental civilian employees? And if later the families of beneficiaries already on the rolls are placed among the elect, the step will not have gone much farther.

State medicine in this obnoxious form is with us, and is tending to grow under the patronage of the federal government. Physicians and private hospitals even now must compete with the federal government for the practice of those whose disabilities have not originated in government service and who are abundantly able to pay for treatment. If the bill passed by the House of Representatives becomes a law, the private practitioner and the private hospital will have to compete with the government, not only in providing hospital treatment for veterans, but in providing both hospital and outpatient treatment for veterans, contract surgeons, contract dentists and contract nurses. How long such unfair competition will continue is uncertain. But unless the present movement is checked, the outcome is sure: a greater and greater encroachment on the rights of the individual patient and physician.

The House of Delegates has three times passed resolutions voicing its opposition to this type of state medicine. Resolutions, however, accomplish nothing unless backed up by action. That action must come from the rank and file of the physicians throughout the country, who must make known their views to their senators and representatives in Congress. Action must be prompt if the extension of free federal medical service is to be checked.

Current Comment

THE PHYSIOLOGY OF "SECOND WIND"

The effects of exercises of endurance are in some ways comparable to the influence exerted by certain types of disease on the body. When carried to excess, the exercises are accompanied, as McKenzie[1] has described the outcome, by acute constitutional exhaustion, shown in breathlessness, from which recovery is rapid; by fatigue of the whole muscular system, from which a rest of a day or two is necessary, and by the chronic or nerve fatigue known as "staleness" among trainers, from which recovery may be a matter of weeks or even months. If the exercise is sufficiently active, the amount of waste material suddenly thrown into the circulation is greater than can be eliminated by the lungs. The breathing becomes rapid and shallow, the pulse quick and fluttering, and the person feels a sense of constriction around the chest; his head swims and throbs, and his face takes on the anxious expression so eloquently telling of the thirst for air. It is a familiar experience, particularly in the running of a race, that after some time the runner may become less distressed than at an earlier period. He is now said to have his "second wind," and can usually continue running with comparative comfort. Varied explanations have been offered for this phenomenon of relief, apparently representing a better equilibrium between the production of waste and its elimination. Thus it is suggested that, as a result of the production of metabolites in the contracting muscles, their vessels may be more dilated, so that the flow of blood through them becomes easier. There is an improvement of the pulse rate and decrease in the respiratory distress. With the advent of "second wind," the urgency of breathlessness fades. The characteristic look of distress disappears from the face, the head becomes clear, and the muscles perform with renewed vigor and elasticity. A runner can then continue his exercise until he feels the symptoms of general fatigue. In observations made in the Department of Physiology of the University of Pennsylvania, Berner, Garrett, Jones and Noer[2] have noted that the subjective sensation of "second wind" unquestionably comes earlier, the warmer the room conditions and the heavier the work done. The subjective sensations are confirmed by records of the respiratory changes, which show similar effects. The increase in the volume of air breathed with exercise occurs more rapidly in a warm than in a cold room. Neither of these variations appears to be dependent on changes in deep body temperature in the trunk, since at this time the rectal temperature is scarcely altered. As it has been demonstrated that the temperature of the muscles in the limbs is considerably below that of the rectum, the most reasonable hypothesis seems to be that the rate at which the muscle develops its full power to remove lactic acid is determined by its temperature, and that the temperature of the muscle reaches its optimum earlier when the metabolism is high with heavy work, or when the surrounding air is warm. Heavy clothing often facilitates the onset of second wind in vigorous exercise; hence warm weather may not be unfavorable to it.

TRAINED NURSES

A report published in the Chicago *News* indicates that the Illinois State Association of Nurses, first district, has just put into effect a new policy under which its members are refusing to accept twenty-four hour duty when called on as private nurses by patients in hospitals. The demand means that a person requiring continuous attendance must employ two nurses where formerly he paid only one. For at least five years there has been increasing uneasiness among the medical profession and the public over the changing attitude of the nurse toward her vocation and her labor. What was formerly distinctly an auxiliary in the care of the sick has become split into a dozen professions and specialties, with increasing attention to management and decreasing attention to individual service. There are now nurses engaged in public health work, social service, laboratory technic, mental investigation, dietetics, roentgenology, anesthesia, hospital management, teaching and many other positions. Too few nurses who enter the training school have their thoughts focused on the ideal of personal service to ailing humanity. Rather, it would seem, they are stimulated to the securing of one of the dignified positions that lie within the categories mentioned. Obviously, by this development, the care of the individual sick person has suffered. The possible lack of this care is responsible for the unrest that pervades medical and lay circles in the matter of nursing. At the last annual session of the American Medical Association, the House of Delegates particularly requested the Board of Trustees to look into the nursing situation and to appoint a special committee for the purpose. On previous occasions, other investigative bodies have rendered reports. Granted that there is need for such highly specialized nursing administration as has been mentioned, the needs of the individual sick are primary ones. Apparently, nurses are being trained in technical matters to a point at which dignity suffers when they are asked to undergo the tribulations of personal service. The modification of curriculums should tend to the development of more nurses who will consider the care of the sick their highest ideal.

REGISTRATION UNDER THE HARRISON NARCOTIC ACT

Registration under the Harrison Narcotic Act must be renewed on or before June 30 by physicians desiring to continue to administer, dispense or prescribe narcotics. In registering this year, physicians will receive for the first time the benefit of the reduction in the tax, from $3 to $1. Thus they will save approximately a quarter million dollars through the work of the American Medical Association in securing this reduction. Failure to register carries with it liability to fine and imprisonment, and subjects the tardy registrant to a 25 per cent increase in his tax. A physician desiring the right to distribute, dispense and administer narcotic drugs of all kinds must register in class 4, but a physician who desires the right to dispense the so-called exempt narcotic preparations must register also in class 5. Registration in class 5 is not required of physicians *who only prescribe exempt preparations and do not dispense them.* A physician registered in class 4 pays no additional tax for registration in class 5, but a physician registering only in class 5 pays a tax of $1. The so-called exempt narcotic preparations include such as contain not more than 2 grains of opium, or more than one-fourth grain of morphine, or more than one-eighth grain of heroin, or more than 1 grain of codein, or any salt or derivative of any of them in 1 fluidounce, or, if a solid or semisolid preparation, in 1 avoirdupois ounce; and liniments, ointments or other preparations that are prepared for external use only, except such as contain cocaine, or alpha or beta eucaine, or the salt of, or any synthetic substitute for, any of them. A preparation to be exempt, however, must contain *active medicinal drugs other than narcotics. Dilutions* of narcotic drugs made by mixing them with inert substances are not within the exempted class.

Rise of Mental Therapy.—The waves of popularity which have marked the progress of mental therapy are an instructive object lesson. Animal magnetism rose to an immense vogue and fell, hypnotism has risen and declined at least twice, Couéism and autosuggestion are at the apex of the wave today, and a closely allied surge may be seen in the astonishingly immense developments of Christian science, New Thought and other doctrines. It may be concluded that all these movements derive their temporary vitality from the undoubted fact that they do produce results, and therefore include somewhere within them principles of actual objective validity. We may call these principles faith and suggestion, but in this wide sense such terms are little more than a cloak for our ignorance. Whatever these principles may be, it is clear that they are of vital concern to medicine, and it is the duty of medicine to dissect them out from their trappings and allot them a defined place in our therapeutic armory.—Hart, Bernard: *Lancet* **1**:589 (March 20) 1926.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

Personal.—Dr. Thomas W. Woodul has been appointed assistant city physician of Pine Bluff.——Dr. Dewell Gann, Jr., Little Rock, recently received the fellowship degree of the Royal College of Surgeons of Edinburgh.——Dr. John C. Swindle has been elected city health officer of Walnut Ridge to succeed Dr. George Max Watkins, resigned.

State Board Election.—At a special meeting of the state board of health, May 17, Dr. Andrew S. Gregg, Fayetteville, was elected president to succeed Dr. Elam H. Stevenson, Fort Smith, and Dr. Rutial O. Norris, Tuckerman, vice president. A committee was appointed to investigate and make recommendations to the board concerning proposed changes in the regulation of dairies and slaughterhouses.

DISTRICT OF COLUMBIA

Reports of Venereal Disease.—The district health officer has issued a circular letter to physicians of the district drawing attention to the reporting of names of patients who have venereal disease. The commissioners formerly instructed the health officer that, for the present, at least, the names of patients with venereal disease, required by a recent law, would not be insisted on, except those who wilfully failed or refused to comply with the directions of physicians to prevent the spread of the disease. The health officer has not, therefore, required the reporting of names. The commissioners have revoked their former instructions to the health officer in this regard. The health officer now requests, therefore, the support of all physicians in carrying out this provision of the law (The Journal, March 21, 1925).

ILLINOIS

Personal.—Dr. Marion K. Bowles, Joliet, was elected president of the Illinois Business and Professional Women's Association at the annual meeting at Aurora, May 22, succeeding Dr. Annie I. Glidden, Danville.——Dr. Perry H. Wessel has been elected president of the Moline Physicians Club for the ensuing year.——Dr. Noble Van Zant, Grant Park, has accepted a position at the American Hospital at Monrovia, Liberia, which is operated by the American Lutheran Mission in conjunction with the Firestone Rubber Company.

Hospital News.—Contracts have been let for the construction of a fourth floor addition to the Lutheran Hospital, Moline, which will be the first unit of an expansion program to be carried out within the next two years.——The new Mercyville Sanatorium for mental diseases at Aurora, operated by the Sisters of Mercy, was recently dedicated; Dr. Henry J. Gahagan will be the medical director.——The Sisters of Mercy of the Holy Cross have sold the Mercy Hospital, Urbana, to the Servants of the Holy Heart of Kankakee for $200,000, it is reported.——Dr. Edwin S. Hamilton, Kankakee, has been elected president of the staff of St. Mary's Hospital for the ensuing year.

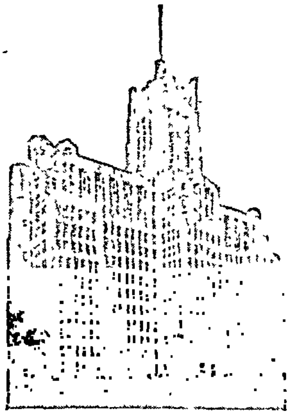
Appraisal of Health Services.—The state department of health, last year, conducted surveys of the health services in fifteen Illinois cities ranging in population from 30,000 to 80,000. A report of these surveys makes up the May-June number of *Illinois Health News*. The standards used in this work were those developed by the American Public Health Association, which assigns a value to each of forty-six items of health service, the total score making [illegible] points. A large part of the work was done by Dr. Th [illegible] an, Jr., U. S. Public Health Service, who was assi [illegible] John W. H. Pollard, Dr. Samuel S. Winner [illegible] The rating given the cities varied from 812 poi [illegible] on to 415 points for East St. Louis, and in the [illegible] : Evanston, Rockford, Decatur, Springfield, O [illegible] Moline, Cicero, Aurora, Quincy, Rock Islan [illegible] Danville, Joliet and East St. Louis. The re [illegible] the cities at the top of the list [illegible] placed their [illegible] ments on a scientific rather [illegible] olitical [illegible] the greatest handicap to m [illegible] ic he [illegible] Illinois arises from the influ [illegible] part

Chicago

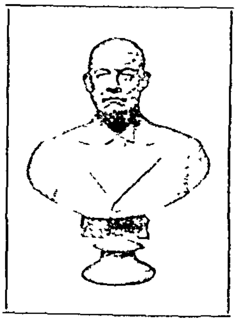
Week of Special Clinics at Rush.—Rush Alumni and friends are cordially invited to attend the special clinics at Rush Medical College from June 14 to June 18. There is a large variety of clinics being given by members of the faculty.

Medical and Dental Arts Club.—More than 400 members and guests of the Medical and Dental Arts Club attended the dinner, May 27, given at the Sherman Hotel, at the close of which the president, Dr. John S. Nagel, announced that the full quota of life memberships at $1,250 had been exhausted and that the price had been advanced to $1,500. A large number of requests for membership were received at the dinner. Dr. Frank Billings, who spoke on "What a Permanent Home Will Mean to Chicago Physicians," said that he would devote his best efforts toward the realization of this home; Dr. Charles N. Johnson, D.D.S., spoke on "What a Permanent Home will Mean to the Chicago Dental Profession"; Dr. Charles J. Whalen, on "A Center for Our United Professions"; Dr. Charles E. Humiston, "A Professional Building a Demonstration to the Public"; Dr. Edward H. Ochsner, "The History of the Movement." Razing of the old building on the site of the new will probably begin, July 1.

Northwestern's New Medical School.—The exterior of the Montgomery Ward Memorial Medical-Dental Center on the McKinlock Campus of Northwestern University having been completed, the cornerstone was laid with appropriate ceremonies, June 11. Dr. Charles H. Mayo of the class of 1888 gave an address on the campus in the afternoon, and Dr. Frank Billings of the class of 1881 at the banquet in the evening. There was a luncheon at the Furniture Mart, near the campus, to which the several faculties and alumni were invited. Among other documents placed in the cornerstone were a list of the faculty of the medical school from its founding in 1859 to date, a list of all graduates arranged by classes, and a list of the names of the present student body. The new building will be occupied, October 1, and dedicatory exercises will be held later when the auditorium is completed.



Bust of Dr. Talbot.—A marble bust of the late Dr. Eugene S. Talbot was presented to the American Medical Association, June 4, at a meeting in the assembly hall of relatives and friends, and officers of the association. Two friends of many years made the presentation speeches; Dr. George Van Ingen Brown, of Milwaukee, said there was no need of marble to perpetuate the memory of a life so helpful and so well known throughout the civilized world; Dr. Frank Billings spoke of the character and ideals of Dr. Talbot; of his long life of work in the Association and his part in establishing the Section on Stomatology. Dr. Edward B. Heckel, Pittsburgh, chairman of the Board of Trustees, in accepting the bust on behalf of the American Medical Association, said that we are glad to have this concrete evidence of the esteem in which Dr. Talbot was held, but that his ideals would endure longer than the marble itself. The original of the bust stands at the entrance of the stomatologic department [illegible] the University of Italy in Rome. It was made for the [illegible] government by the sculptor Ernesto Gazzero (The [illegible] Dec. 20, 1924).



IOWA

[illegible] d **Commits Suicide.**—James W. McLen- [illegible] red diploma mill "Oskaloosa College," [illegible] re found dead in the gas-filled base- [illegible] at Oskaloosa, May 8, following [illegible] a charge of using the mails to [illegible] the issuance of degrees and [illegible] to have established a correspondence school in Oskaloosa, using the name of the old, but now nonexistent, Oskaloosa College. After a course of study "in absentia," it was the practice of the school to issue certificates purporting to be diplomas to school teachers, ministers and others, conferring, it is reported, "doctor's degrees in everything from pedagogy to chiropody." Letters found in the home revealed that McLennan and his family died in a suicide pact because they lacked funds to fight what they described as an "unjust charge."

MAINE

State Medical Meeting.—The Maine Medical Association will meet at Poland Springs, June 10-12, under the presidency of Dr. Joseph D. Phillips, South West Harbor. Dr. John B. Deaver, Philadelphia, will speak Friday afternoon on "Surgical Versus Medical Treatment of Gallbladder Diseases." Dr. Wendell C. Phillips, New York, president, American Medical Association, will deliver the address at the banquet Friday evening, and on Saturday there will be a symposium on obstetrics, under the direction of Dr. Foster S. Kellogg, Boston, assisted by Drs. Leonard H. Ford, Bangor; Harold W. Garcelon, Auburn; Adam P. Leighton, Jr., Portland, and Ralph L. Reynolds, Waterville.

MARYLAND

Board of Mental Hygiene.—The annual meeting of the state board of mental hygiene and the boards of managers of the state hospitals for the insane and feebleminded with the governor and the director of welfare was held, May 25, at the Spring Grove State Hospital, Catonsville. Dr. Arthur P. Herring, commissioner of mental hygiene, reviewed briefly the work of the board since its organization in 1888, and the building program which the board is planning to submit to the general assembly in January, 1927. A report on the needs of each state hospital was made by the respective superintendents. The discussion was opened by Governor Ritchie.

MASSACHUSETTS

Summer Courses at Institute of Technology.—The Massachusetts Institute of Technology, Boston, recently announced that summer courses in public health and biology will be given from July 6 until August 17. The courses include (1) general bacteriology, (2) methods of teaching general biology, (3) public health laboratory methods, (4) health education methods, and (5) health records and statistical procedure.

Investigation of Workmen's Compensation Act.—The governor has signed a resolution for the appointment of a special commission to investigate the operation of the workmen's compensation law. There will be five citizens of the state on the commission, all unpaid, who will determine the effect of the present law, and what changes, if any, seem necessary. The commission is authorized to expend not more than $2,500 for assistants, and will report not later than December 1.

Summer Clinical Courses at Harvard.—In addition to the laboratory courses mentioned in THE JOURNAL, May 15, Harvard Medical School, Boston, offers to graduates clinical courses in such subjects as surgery, anesthesia, obstetrics and gynecology, dermatology, diseases of the nervous system, pediatrics, and various other specialties. Information concerning these courses may be obtained from Dr. Samuel R. Meaker, secretary of graduate courses at the medical school, 240 Longwood Avenue, Boston.

Physicians' Home Benefit Concert.—An operatic concert was given at the Boston Opera House, Boston, May 24, for the benefit of the Physicians' Home, Inc., and to aid in the purchase of the estate of the late Col. Edward N. Knox, known as Downsbury Manor, in Connecticut. The artists were Frances Alda, Dorothea Flexer, Giovanni Martinelli, Giovanni Martino and Albert Spalding. Allan Forbes, 120 Boylston Street, Boston, is treasurer for Massachusetts in the campaign to raise funds for the Physicians' Home.

Society News.—Dr. Philemon E. Truesdale addressed the North Bristol District Medical Society recently on "Peptic Ulcer," illustrated by lantern slides.——The next meeting of the New England Surgical Society will be in Boston about October 1.—Dr. Joseph J. Skirball, Boston, addressed the North Shore Medical Fraternity, Lynn, May 20, on "Some Common Eye Conditions as Seen by the General Practitioner," illustrated with lantern slides, and Dr. William D. McFee, Haverhill, April 20, on "Uses of Physiotherapy in General Practice."

MISSISSIPPI

Personal.—Dr. Solomon R. Boykin, Mize, has been appointed superintendent of the State Charity Hospital at Jackson.——The residence of Dr. William H. Aikman, health officer of Natchez and Adams County, was destroyed by fire, recently.

State Medical Election.—At the annual meeting of the Mississippi State Medical Association, Jackson, May 11-13, Dr. Theophilus E. Ross, Sr., Hattiesburg was elected president; and Drs. Roland W. Hall, Jackson, Ellis L. Wilkins, Clarksdale, and Charles E. Catchings, Jr., Woodville, vice presidents. Dr. Thomas M. Dye is the secretary; the next meeting will be held at Vicksburg. The contract with the *New Orleans Medical and Surgical Journal* was renewed for two years. Mrs. William H. Frizell, Brookhaven, was elected president-elect of the Women's Auxiliary.

MISSOURI

Personal.—Dr. H. L. Mantz, Kansas City, has been appointed superintendent of the Leeds Tuberculosis Sanatorium, which is a branch of the health department of Kansas City.——Dr. Charles H. Wallace, St. Joseph, has filed as a candidate for state representative from Buchanan County.——Dr. Cecil L. Wayman was appointed tuberculosis controller of St. Louis, April 1, to succeed Dr. Hyman I. Spector; Dr. Wayman was formerly with the U. S. Veterans' Bureau at St. Louis.——Dr. Richard L. Sutton, Kansas City, received the honorary degree of doctor of science from Washburn College, Topeka, Kan., June 2.

Hospital News.—The Christian Church Hospital, Kansas City, has been leased to the U. S. Veterans' Bureau; June 30, the Veterans' Bureau will vacate the Wesley Hospital, which was formerly operated by Dr. James A. Robertson, who announces that he will reopen the Wesley Hospital about August 1, and that Dr. Rush E. Castelaw, formerly superintendent, will return from Williamsport, Pa., and again assume the superintendency of Wesley Hospital.——Dr. Porter E. Williams has taken up the duties of superintendent of the Kansas City General Hospital; Dr. George C. Lee is the assistant superintendent.

Clinic for Crippled Children.—A clinic for crippled children was held at New Madrid, recently, under the auspices of the New Madrid County Health Unit. About twenty physicians volunteered their services; the railroads furnished free transportation and hospitals in St. Louis free beds during convalescence from operations to correct the deformities. Twenty crippled children will be sent to hospitals. Following the crippled children's clinic there was an eye clinic and a tonsil and adenoid clinic. This work is all free for those who are unable to pay, and such clinics have been held at least once a year since the county health unit was organized in 1922.

Society News.—Dr. Hugh H. Young, clinical professor of urology, Johns Hopkins University Medical School, addressed the Jackson County Medical Society, Kansas City, recently. ——Dr. B. Brouwer, professor of neurology, University of Amsterdam, Holland, addressed the St. Louis Medical Society, May 11, on "The Pathology of Sensibility."——Mrs. J. F. Shoemaker, wife of a member of the St. Louis Medical Society, has donated $5,000 toward the completion of the new auditorium. The society held its final meeting in the old building at 3525 Pine Street, June 1; Dr. Alonzo R. Kieffer spoke on the details of the construction of the auditorium. There was also a moving picture program.——Dr. Jabez N. Jackson, President-Elect of the American Medical Association, and Mrs. Jackson were guests of honor, May 8, at a reception given by the Jackson County Medical Society and the Women's Auxiliary at the residence of Dr. and Mrs. George Wilse Robinson, Kansas City.

School to Develop Speakers.—There will be a Kansas City Public Health Institute, under the auspices of the Health Conservation Association, beginning about the middle of June, the purpose of which will be to develop public speakers for public health and allied subjects. Those who complete this course satisfactorily will comprise the Speakers' Bureau of the Health Conservation Association and probably of the Jackson County Medical Society. There will be at least ten sessions covering various phases of hygiene and preventive medicine; the visiting speakers will include, among others, Drs. John M. Dodson and Herman N. Bundesen, both of Chicago; Dr. Charles P. Emerson, Indiana University School of Medicine, Indianapolis; Dr. Iago Galdston, New York, and Dr. Mazyck P. Ravenel, of the University of Missouri

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

Personal.—Dr. Thomas W. Woodul has been appointed assistant city physician of Pine Bluff.——Dr. Dewell Gann, Jr., Little Rock, recently received the fellowship degree of the Royal College of Surgeons of Edinburgh.——Dr. John C. Swindle has been elected city health officer of Walnut Ridge to succeed Dr. George Max Watkins, resigned.

State Board Election.—At a special meeting of the state board of health, May 17, Dr. Andrew S. Gregg, Fayetteville, was elected president to succeed Dr. Elam H. Stevenson, Fort Smith, and Dr. Rutial O. Norris, Tuckerman, vice president. A committee was appointed to investigate and make recommendations to the board concerning proposed changes in the regulation of dairies and slaughterhouses.

DISTRICT OF COLUMBIA

Reports of Venereal Disease.—The district health officer has issued a circular letter to physicians of the district drawing attention to the reporting of names of patients who have venereal disease. The commissioners formerly instructed the health officer that, for the present, at least, the names of patients with venereal disease, required by a recent law, would not be insisted on, except those who wilfully failed or refused to comply with the directions of physicians to prevent the spread of the disease. The health officer has not, therefore, required the reporting of names. The commissioners have revoked their former instructions to the health officer in this regard. The health officer now requests, therefore, the support of all physicians in carrying out this provision of the law (The Journal, March 21, 1925).

ILLINOIS

Personal.—Dr. Marion K. Bowles, Joliet, was elected president of the Illinois Business and Professional Women's Association at the annual meeting at Aurora, May 22, succeeding Dr. Annie I. Glidden, Danville.——Dr. Perry H. Wessel has been elected president of the Moline Physicians Club for the ensuing year.——Dr. Noble Van Zant, Grant Park, has accepted a position at the American Hospital at Monrovia, Liberia, which is operated by the American Lutheran Mission in conjunction with the Firestone Rubber Company.

Hospital News.—Contracts have been let for the construction of a fourth floor addition to the Lutheran Hospital, Moline, which will be the first unit of an expansion program to be carried out within the next two years.——The new Mercyville Sanatorium for mental diseases at Aurora, operated by the Sisters of Mercy, was recently dedicated; Dr. Henry J. Gahagan will be the medical director.——The Sisters of Mercy of the Holy Cross have sold the Mercy Hospital, Urbana, to the Servants of the Holy Heart of Kankakee for $200,000, it is reported.——Dr. Edwin S. Hamilton, Kankakee, has been elected president of the staff of St. Mary's Hospital for the ensuing year.

Appraisal of Health Services.—The state department of health, last year, conducted surveys of the health services in fifteen Illinois cities ranging in population from 30,000 to 80,000. A report of these surveys makes up the May-June number of *Illinois Health News*. The standards used in this work were those developed by the American Public Health Association, which assigns a value to each of forty-six items of health service, the total score making 1,000 points. A large part of the work was done by Dr. Thomas Parran, Jr., U. S. Public Health Service, who was assisted by Dr. John W. H. Pollard, Dr. Samuel S. Winner and others. The rating given the cities varied from 812 points for Evanston to 415 points for East St. Louis, and in the following order: Evanston, Rockford, Decatur, Springfield, Oak Park, Peoria, Moline, Cicero, Aurora, Quincy, Rock Island, Bloomington, Danville, Joliet and East St. Louis. The report states that the cities at the top of the list have placed their health departments on a scientific rather than a political basis, and that the greatest handicap to municipal public health work in Illinois arises from the influence of local partisan politics.

Chicago

Week of Special Clinics at Rush.—Rush Alumni and friends are cordially invited to attend the special clinics at Rush Medical College from June 14 to June 18. There is a large variety of clinics being given by members of the faculty.

Medical and Dental Arts Club.—More than 400 members and guests of the Medical and Dental Arts Club attended the dinner, May 27, given at the Sherman Hotel, at the close of which the president, Dr. John S. Nagel, announced that the full quota of life memberships at $1,250 had been exhausted and that the price had been advanced to $1,500. A large number of requests for membership were received at the dinner. Dr. Frank Billings, who spoke on "What a Permanent Home Will Mean to Chicago Physicians," said that he would devote his best efforts toward the realization of this home; Dr. Charles N. Johnson, D.D.S., spoke on "What a Permanent Home will Mean to the Chicago Dental Profession"; Dr. Charles J. Whalen, on "A Center for Our United Professions"; Dr. Charles E. Humiston, "A Professional Building a Demonstration to the Public"; Dr. Edward H. Ochsner, "The History of the Movement." Razing of the old building on the site of the new will probably begin, July 1.

Northwestern's New Medical School.—The exterior of the Montgomery Ward Memorial Medical-Dental Center on the McKinlock Campus of Northwestern University having been completed, the cornerstone was laid with appropriate ceremonies, June 11. Dr. Charles H. Mayo of the class of 1888 gave an address on the campus in the afternoon, and Dr. Frank Billings of the class of 1881 at the banquet in the evening. There was a luncheon at the Furniture Mart, near the campus, to which the several faculties and alumni were invited. Among other documents placed in the cornerstone were a list of the faculty of the medical school from its founding in 1859 to date, a list of all graduates arranged by classes, and a list of the names of the present student body. Dr. Edward B. Heckel, Pittsburgh, chairman of the Board of Trustees, in accepting the bust on behalf of the American Medical Association, said that we are glad to have this concrete evidence of the esteem in which Dr. Talbot was held, but that his ideals would endure longer than the marble itself. The original of the bust stands at the entrance of the stomatologic department of the University of Italy in Rome. It was made for the Italian government by the sculptor Ernesto Gazzero (The Journal, Dec. 20, 1924).

IOWA

Diploma Mill Head Commits Suicide.—James W. McLennan, head of the alleged diploma mill "Oskaloosa College," and his wife and son, were found dead in the gas-filled basement of their residence at Oskaloosa, May 8, following McLennan's indictment on a charge of using the mails to defraud in connection with the issuance of degrees and diplomas. McLennan is said to have established a correspondence school in Oskaloosa, using the name of the old, but now nonexistent, Oskaloosa College. After a course of study "in absentia," it was the practice of the school to issue certificates purporting to be diplomas to school teachers, ministers and others, conferring, it is reported, "doctor's degrees in everything from pedagogy to chiropody." Letters found in the home revealed that McLennan and his family died in a suicide pact because they lacked funds to fight what they described as an "unjust charge."

MAINE

Shoemaker, wife of a member of the St. Louis Medical Society, has donated $5,000 toward the completion of the new auditorium. The society held its final meeting in the old building at 3525 Pine Street, June 1; Dr. Alonzo R. Kieffer spoke on the details of the construction of the auditorium. There was also a moving picture program.—— Dr. Jabez N. Jackson, President-Elect of the American Medical Association, and Mrs. Jackson were guests of honor, May 8, at a reception given by the Jackson County Medical Society and the Women's Auxiliary at the residence of Dr. and Mrs. George Wilse Robinson, Kansas City.

School to Develop Speakers.—There will be a Kansas City Public Health Institute, under the auspices of the Health Conservation Association, beginning about the middle of June, the purpose of which will be to develop public speakers for public health and allied subjects. Those who complete this course satisfactorily will comprise the Speakers' Bureau of the Health Conservation Association and probably of the Jackson County Medical Society. There will be at least ten sessions covering various phases of hygiene and preventive medicine; the visiting speakers will include, among others, Drs. John M. Dodson and Herman N. Bundesen, both of Chicago; Dr. Charles P. Emerson, Indiana University School of Medicine, Indianapolis; Dr. Iago Galdston, New York, and Dr. Mazyck P. Ravenel, of the University of Missouri

School of Medicine. The number of matriculates for the institute is limited to fifty; certificates will be awarded those who pass an examination when the course is finished. Applications should be sent to Mrs. Ettella L. Kelly, executive secretary, 420 Hall Building, Kansas City.

NEW MEXICO

State Medical Election.—At the annual meeting of the New Mexico Medical Society, May 19-21, Dr. Charles F. Beeson, Roswell, was elected president; Dr. Cary B. Elliott, Raton, president elect; Dr. Dwight Allison, Las Cruces, vice president, and Dr. Charles M. Yater, Roswell, secretary-treasurer; the next annual meeting will be at Carlsbad.

NEW YORK

Report of Gun-Shot Wounds.—The governor has signed a bill requiring physicians to report to the police, immediately, cases of gun-shot wounds, and making the failure to make a report a misdemeanor.

Dr. Brown Resigns.—Dr. William P. Brown, medical director, Rocky Crest Sanatorium, and assistant director, Bureau of Tuberculosis, Cattaraugus County Board of Health, resigned, effective, June 1, and accepted the medical secretaryship of the Pennsylvania State Tuberculosis Society.

Hospital Resignations.—Fourteen physicians on the staff of the Oswego Hospital were reported to have resigned, May 15, in protest at the refusal of the trustees to reinstate two members of the staff who had been suspended for criticizing the hospital management, it is reported, in public addresses.

Veteran Physicians Honored.—The Ulster County Medical Society, Kingston, gave a testimonial dinner, June 3, to the physicians in the county who have practiced medicine at least fifty years. The guests of honor were Drs. James R. Nelson, Abraham P. Chalker, Henry Van Hoevenberg, Elbert H. Loughran and George C. Basten, all of Kingston, and Dr. Benjamin F. Neal, Ellenville, and Dr. Rufus Crawford, Saugerties. These veterans, all near 80 years of age, recalled before the society the pleasures and difficulties of medical practice fifty years ago, and the advances made in medical practice in that time. Dr. Loughran was toastmaster. The president of the society is Dr. Mary Gage Day.

Opposition to Treatment by a Corporation.—The Medical Society of the County of New York unanimously adopted the following resolution, May 24:

Whereas, It has come to the attention of this society that the New York Tuberculosis Association, Inc., as an inducement to obtain additional members therein, has made the following representations to the public, to wit:

"The New York Tuberculosis and Health Association, Inc., offers free information and advice on all health problems and expert chest examination with x-ray facilities at cost to employees of offices, stores and factories—Arrangements made for placement in suitable institutions when necessary"; and

Whereas, It is understood that Mr. Harry O. Hopkins, director of the association, has stated that the price of the expert chest examination with x-ray facilities is to be $15; and

Whereas, A corporation is expressly forbidden to practice medicine by the laws of the state of New York; and

Whereas, Said representation made to the public leaves the cost of such proposed treatment vague and uncertain, although known to the association; and

Whereas, Such treatment, stated to be at cost, is to be given to a group of employees, irrespective of their ability to pay therefor, many of whom can readily afford to obtain such advice and treatment from their family physicians; and

Whereas, No provision is contained in such proposal to limit such treatment and advice to those persons referred to the association by practicing physicians; and

Whereas, In the opinion of this society, such proposal, if carried out as made, would not be to the best interests of the profession or of the public; now, therefore, be it

Resolved, That the Medical Society of the County of New York is opposed to and protests against the carrying out of such proposal as made by the New York Tuberculosis and Health Association, Inc.

New York City

University News.—The Long Island College Hospital granted the degree of doctor of medicine to ninety graduates at the commencement exercises at the Academy of Music, June 3; this is said to be the largest class graduated since the school was founded, sixty-seven years ago.

Dentist Fined for Practicing Medicine.—Bertram Ball, D.D.S., was fined $500, June 4, according to the New York *Times,* for practicing medicine illegally. Dr. Ball's attorney announced that the case would be taken to the U. S. Supreme Court, if necessary, to test the constitutionality of the state law. Dr. Ball is said to have prescribed medicine for the kidneys of a patient he treated for pyorrhea.

Dinner to Sir Arthur Newsholme.—The board of council of the Milbank Memorial Fund tendered a dinner at the Hotel Biltmore in honor of Sir Arthur Newsholme of London, previous to his sailing for home, recently; among the guests present were Dr. William H. Welch, Baltimore; Dr. Hugh S. Cumming, Washington, D. C.; Dr. Livingston Farrand; Dr. Matthias Nicholl, Jr.; Dr. Louis I. Harris; Dr. Linsly R. Williams; Cornelius N. Bliss, Jr., A.B.; Edward M. Sheldon and Albert G. Milbank.

Free Cancer Clinics.—Commissioner of Welfare Bird S. Coler announced, May 12, that the city's free service for the treatment of cancer under the New York Cancer Institute will be extended to the East Harlem Health Center, 345 East One Hundred and Sixteenth Street, the New York Dispensary, 34 Spring Street, and the Bowling Green Neighborhood Association, 105 Washington Street, and that at each place medical and nursing attendance will be provided. Mr. Coler is reported to have said that New York is the only city in the world giving radium, roentgen-ray and electrotherapeutic treatments free of cost.

Personal.—Dr. George J. Doyle has been appointed chief medical examiner for the Municipal Civil Service Commission to succeed the late Dr. Joseph A. Kene.——Attorney William B. Groat, Hollis, has been appointed, by the attorney general of the state, deputy state attorney general in charge of the prosecution of illegal practitioners under the new medical practice act recently signed by the governor.—Dr. Nathan E. Broder has been appointed associate obstetrician to the People's Hospital.——The Surgeon General, U. S. Army, has recommended to the war department that Dr. Haven Emerson, colonel medical reserve corps, among others, be assigned to active duty for fifteen days from June 16, and directed to proceed to Carlisle Barracks, Pa., for training; Dr. William J. Francis, major, M. O. R C., was ordered to active duty for forty-five days' training at Mitchel Field, L. I., effective, May 1.——Dr. Antonio Fanoni has been decorated by the king of Italy knight commander of the Order of the Crown of Italy for his work for the Italian Hospital in New York and for benefactions to his native town, Settefrati, Italy.

NORTH DAKOTA

State Medical Election.—At the thirty-ninth annual meeting of the North Dakota State Medical Association, Minot, May 25-26, Dr. N. Oliver Ramstad, Bismarck, was elected president; Dr. Thomas Mulligan, Grand Forks, president-elect; Drs. William F. Sihler, Devils Lake, and John Crawford, New Rockford, vice presidents; Dr. Alexander J. McCannel, Minot, secretary, and Dr. William W. Wood, Jamestown, treasurer. The names of Drs. Henry H. Healy, Grand Forks, Henry M. Waldren, Drayton, and Murdock MacGregor, Fargo, were recommended to the governor for reappointment on the state board of medical examiners. The next meeting of the state medical association will be in Grand Forks in May, 1927.

OHIO

Hospital News.—The Flower Hospital, Toledo, will occupy its new ninety bed addition within the next few days; this will make the capacity of the hospital 150 beds.——The Longview Hospital and Hamilton County Infirmary, Cincinnati, which were recently purchased by the state, will be merged and known as the Longview State Hospital.——Dr. Wilbur M. Warner has been elected president of the staff of Middletown Hospital, Middletown, to succeed Dr. John C. Stratton.

Medals for Golf Champions.—At the sixth annual tournament of the Ohio State Medical Golfers' Association, Toledo, May 10, gold medals were presented to winners of championships for the last six years; the champion heretofore was awarded the Championship Cup, temporarily. Medals were thus presented to Dr. William D. Inglis, Columbus, winner in 1921; Dr. Earl E. Gaver, winner in 1922 and 1923; Dr. William H. Fisher, Toledo, 1924; Dr. Ralph R. Wilkinson, Cincinnati, 1925, and Dr. Thomas F. Heatley, Toledo, 1926. At the golfers' banquet following the tournament, Dr. E. Otis Smith, Cincinnati, was elected president of the association for 1927.

The Automobile a Major Health Problem.—In his annual report, the commissioner of health of Cleveland credits automobile traffic in that city as the cause of 226 deaths and 4,520 nonfatal injuries in 1925. The increase in automobile traffic, he says, is one of the most important causes of the increase in the number of cripples in the community; it was of far more importance than infantile paralysis, which caused twenty deaths in eighty-eight cases, and of far more importance, also, as a health problem than diphtheria, which caused 138 deaths in 1,746 cases. In a list of fourteen communicable diseases with the number of deaths that occurred from each, only one disease caused more deaths in Cleveland last year than did the automobile, and that was pneumonia.

OKLAHOMA

Increase of Rabies.—The state department of health, in a recent bulletin, notes that the state laboratory examined the heads of 264 dogs from January 1 to May 21, and that seventy-one were positive for rabies; also that 256 Pasteur treatments had been sent out by the laboratory since January 1. There were fourteen deaths from rabies in Oklahoma in 1925. It is necessary now, that indigent persons may receive Pasteur treatment free and without delay, for the commissioners of each county to designate some physician, druggist or health officer as agent who shall be authorized to purchase the treatment from the state laboratory, to be reimbursed by the county; formerly treatment was furnished free to all indigent persons.

PENNSYLVANIA

Personal.—Dr. John W. Shirer won the prize offered by the Allegheny County Medical Society for the best case report submitted by an intern in any hospital in Allegheny County (The Journal, February 20).——Dr. Amos M. Pierce, West Elizabeth, was recently given an ovation by the Valley Medical Society on the completion of his fiftieth year in the practice of medicine.——Dr. John E. Barsby, Chester, has been engaged by the Delaware County Tuberculosis Association to take charge of the regional clinic service and industrial health service.

Fifth Councilor District Meeting.—A scientific and social meeting of physicians of the Fifth Councilor District of the Medical Society of the State of Pennsylvania will be held June 16, 10:30 a. m., at the Huntingdon Country Club, Huntingdon, to which all reputable physicians are invited. There will be a dinner following the scientific program ($2 per plate). Dr. Harold A. Miller, professor of obstetrics, University of Pittsburgh School of Medicine, and Dr. W. Wayne Babcock, professor of surgery and clinical surgery, Temple University School of Medicine, Philadelphia, will speak on scientific subjects, and among the other guests will be the president, president-elect, and secretary of the state medical society.

Hospital News.—The last sale of Christmas seals in Pennsylvania totaled a little over $500,000; every Pennsylvania tuberculosis organization retains at least 80 per cent of Christmas seal funds, the rest going to the state and national tuberculosis work.——The court of Northampton County handed down the decision, April 5, that the County Tuberculosis Hospital Act of 1925 was constitutional and that the election of Nov. 6, 1923, providing for a bond issue of $200,000 for a tuberculosis hospital in that county, was valid.——McKean County has planned to hold an election in the fall for establishing a tuberculosis sanatorium under the Tuberculosis Hospital Act of 1925.——More than 600 residents of Roxborough and Manayunk attended a dinner, June 2, to open a campaign to raise $250,000 to enlarge the Memorial Hospital, Roxborough (Philadelphia).

Camp of Instruction.—The state department of health will hold its seventh annual camp of instruction, June 21-23, at the Mont Alto Sanatorium. The meeting will be limited largely to the staff of the department and physicians connected with the state tuberculosis clinics, and to a number of representatives from cooperating agencies. The camp will specialize on tuberculosis, emphasing heliotherapy, the advantages of rest, pneumothorax, special nutrition classes and treatment in the home of patients. The speakers will include Drs. Henry R. M. Landis and Eugene Opie of the Henry Phipps Institute; Dr. Stephen A. Douglass of the Milbank Demonstration in Cattaraugus County, N. Y.; Dr. Nathan Barlow, U. S. Veterans' Bureau; Dr. Ward Brinton, director of the tuberculosis division of the Philadelphia Department of Health, and others.

Philadelphia

Society News.—Drs. Reginald Fitz and Frederick M. Allen, Morristown, N. J., addressed the Philadelphia County Medical Society, June 9, on "The Management of the Patient with Chronic Nephritis" and "Renal Vascular Disease: Some Clinical and Experimental Observations," respectively.

Hospital Anniversary.—Dr. Thomas W. Salmon, professor of psychiatry, Columbia University College of Physicians and Surgeons, New York, delivered the address at the one hundred and seventy-fifth anniversary of the Pennsylvania Hospital, May 26; the hospital was incorporated, May 11, 1751, and the first patients admitted, Feb. 10, 1752, one of whom was a mental patient (The Journal, April 10, 1926, p. 1140).

Diphtheria Prevention in Schools.—The board of education, which has started a campaign to immunize pupils in the city schools against diphtheria, expects to complete the work in the West Philadelphia schools and in the schools east of Broad Street and south of Market Street before the present term ends; the campaign will start in the remaining schools at the beginning of the fall term. Dr. Wilmer Krusen, city health commissioner, will supervise the work. Each pupil will be given a coupon to be signed by his parents and presented to the physicians of the board of education at the school before the toxin-antitoxin is administered.

Jefferson Medical College Commencement.—The one hundred and first annual commencement of Jefferson Medical College was held, June 4, in the Academy of Music; the degree of doctor of medicine was conferred on 144 graduates. The honorary degree of doctor of literature was conferred on Dr. Harvey Cushing, professor of surgery, Harvard University, Boston, the principal speaker. Commissions as first lieutenant in the Medical Officers' Reserve Corps, U. S. Army, were presented to forty-nine members of the graduation class. This was the fourth group of Jefferson students to receive commissions in the reserve corps after having completed a course in military training.

UTAH

State Medical Election.—At the annual meeting of the Utah State Medical Association, Salt Lake City, May 8, Dr. William R. Calderwood, Salt Lake City, was elected president; Dr. Eugene H. Smith, Ogden, president-elect; Drs. Edward M. Conroy, Ogden, Frank F. Fiske, Price, and Richard A. Pearse, Brigham City, vice presidents; Dr. Frank B. Steele, Salt Lake City, secretary, and Dr. Edward D. Le Compte, Salt Lake City, treasurer.

CANADA

Trudeau-Laennec Meeting.—The Trudeau Society of Michigan and the Laennec Society of Ontario, Canada, held a joint meeting, May 25, at the Queen Alexander Sanatorium, London, Ontario. Dr. Jabez H. Elliott, Toronto, discussed "Recent Books on Tuberculosis and Pulmonary Disease"; Dr. Bruce C. M. Whyte, Battle Creek, Mich., "Bronchiectasis with Reference to Lipiodol Injections," and Dr. Plinn F. Morse, Detroit, "Clinical and Pathologic Findings in Chronic Pneumonitis."

Society News.—The North Pacific Pediatric Society will hold its summer meeting at the Empress Hotel, Vancouver, B. C., June 22; Dr. Willis S. Lemon, Rochester, Minn., will speak on "Bronchiectasis in Childhood"; Dr. J. G. Fitzgerald, University of Toronto Faculty of Medicine, "Diphtheria Toxoid (Anatoxin) as an Immunizing Agent Against Diphtheria"; Dr. Robert H. L. O'Callaghan, Calgary, Alta., "Pneumococcus Peritonitis," and Drs. Harry A. Rawlings and Alfred Howard Spohn, Vancouver, on "Diagnosis and Treatment of Enlarged Thymus."——Dr. Walter Ross Lane, Nanaimo, has been elected president of the No. 6 District Medical Society, and Dr. Thomas L. Butters, Courtenay, vice president; Dr. William D. Keith, Vancouver, addressed the annual meeting of the society recently on "Clinical Problems of Treatment of Goiter."

Canadian Medical Association Meeting.—The fifty-seventh annual meeting of this association will be at Victoria, B. C., June 21-25, with headquarters at the Empress Hotel. The council will meet throughout Monday and Tuesday, and the official opening of the meeting will be Wednesday, when there will be among other scientific discussions a symposium on "Duodenal Ulcer" by Dr. Herbert C. Moffitt, San Francisco, and Drs. William H. Dickson and Frederick N. G. Starr, Toronto, and an address by Dr. Leonard G. Rowntree, Rochester, Minn., on "Progress in Our Knowledge of Kidney and Liver Function in Relation to Disease." Dr. Maude E. S. Abbott, Montreal, will give a lantern slide exhibit, Thursday, on "The Sir William Osler Memorial Volume and Its Classified and Annotated Bibliographies," and, among others, Dr. John F. Barnhill, Indianapolis, will discuss "Some General Diseases Which Have Origin in Infections of the Head." Dr. Frederick G. Banting, Toronto, will discuss "Medical Research," Friday, when there will also be a symposium on goiter by Drs. William D. Keith, Vancouver, Alvah H. Gordon, Montreal, Gordon S. Fahrni, Winnipeg, and W.

Herbert McGuffin, Calgary. There will be extensive entertainment: receptions, luncheons, drives, golf, visits and garden parties, some arranged especially for the women, to assist whom a committee of women will be in attendance daily at headquarters.

GENERAL

New Hospital Headquarters.—The American Hospital Association will move into its new headquarters, 18-22 East Division Street, Chicago, July 1.

Fellowships in Medicine.—In order to receive consideration at the September meeting of the Medical Research Board of the National Research Council, applications for fellowships in medicine should be filed not later than August 1, with the Chairman, Medical Fellowship Board, National Research Council, Washington, D. C.

Accidents at Coal Mines in April.—The bureau of mines reports that 130 men were killed in accidents at coal mines in the United States in April, 101 of whom were killed in bituminous mines and twenty-nine in anthracite mines. The death rate per million tons of coal mined was 2.69, as compared with 3.90 for April, 1925. In the first four months of 1926 there were 814 men killed in the coal mining industry in the United States. There were no major disasters in April, but there were seven in the preceding months of this year, all of which were caused by explosions.

Increase in Rural Health Service.—There were, at the beginning of this year, 307 counties or districts in the United States with local health service under whole-time local health officers; of these 280, or 91 per cent, according to the U. S. Public Health Service, were receiving financial assistance from one or more of the following agencies: the state board of health, the U. S. Public Health Service, the International Health Board, and the Children's Bureau of the U. S. Department of Labor. This number represents a net gain of twenty-seven counties in the year 1925 over the number that had local health service in 1924.

American Academy of Ophthalmology and Oto-Laryngology.—The thirty-first annual meeting of the academy will be at Colorado Springs, Colo., September 13-18, with headquarters at the Antlers Hotel. Mr. Basil Graves, London, England, the guest of honor, will give an address on some phase of slit lamp work. The American Board of Ophthalmic Examinations and the American Board in Oto-Laryngology will probably hold their examinations in Denver, September 13; the Section on Instruction will begin its sessions, September 17, and continue until the 18th. There will be a one-day golf tournament, September 13, for which arrangements can be made by addressing Dr. Frank L. Dennis, 301 Ferguson Building, Colorado Springs.

Decrease in Birth Rates.—Birth rates in 1925 were lower than in 1924 in twenty-six of the thirty states for which figures have been compiled by the bureau of the census, the department of commerce has announced. North Carolina, with a birth rate of 22.8 per thousand of population, shows the highest 1925 birth rate, and Montana, with 15.1 per thousand, shows the lowest. Death rates for 1925 were higher than for 1924 in sixteen of the thirty states shown for both years. The highest 1925 death rate, 14.6 per thousand, is shown for Vermont, and the lowest, 7.7, for Montana and North Dakota. Infant mortality rates for 1925 were generally higher than those for 1924, as nineteen of the thirty states show higher rates in 1925. The highest 1925 infant mortality rate, 90.4, appears for Maryland, and the lowest, 51.2, for Oregon.

International Meeting of Balneologists.—The eighth International Medical Postgraduate Course with special reference to balneology and balneotherapy will be held at Carlsbad, September 12-18. Clinicians and scientists from the medical faculties of Austria, Bulgaria, Czechoslovakia, Denmark, England, Germany, Italy, Norway, Sweden, Switzerland and Turkey will give addresses. The United States will be represented by Dr. Lewellys F. Barker, emeritus professor of medicine, Johns Hopkins University Medical Department, Baltimore. An invitation is extended to all physicians; those who accept will receive a passport visé without charge and a 33 per cent reduction on all state railways in Czechoslovakia. A program of entertainment has been arranged. Programs will be sent on application to Dr. Edgar Ganz, secretary of the Medical Postgraduate course in Carlsbad, Czechoslovakia.

Foot-and-Mouth Disease Eradicated from the United States.—The Department of Agriculture revoked, June 10, all domestic quarantine regulations previously imposed because of foot-and-mouth disease in live stock. Just a year has elapsed since the disease was last found in California; in the meantime there has been no recurrence of the infection there. Texas, where foot-and-mouth disease reappeared in 1925, was officially freed from all quarantine, April 1, 1926. Bureau of Animal Industry order 297, effective, June 10, officially declares that foot-and-mouth disease has been eradicated from the United States. There still remain in effect, however, the usual restrictions, which are rigidly enforced, that protect the United States from foot-and-mouth disease and other live stock plagues in foreign countries. As the result of discovering the disease in hog carcasses from the Netherlands intended for consumption in Great Britain, the British ministry of agriculture and fisheries has prohibited the landing in Great Britain of all carcasses from continental Europe. This is the first time the British government has prohibited the importation of fresh meat on account of foot-and-mouth disease, although for years it has enforced quarantine against live animals from countries in which the disease was present.

Society News.—Dr. Harvey Cushing, Harvard University Medical School, Boston, was elected president of the American Surgical Association, at the annual meeting, Detroit, May 26; Drs. Alexander Primrose, Toronto, and Arthur A. Law, Minneapolis, vice presidents; Dr. Robert B. Greenough, Boston, secretary, and Dr. Eugene H. Pool, New York, treasurer. The next annual meeting will be at Richmond, Va.——Lee K. Frankel, Ph.D., New York, was elected chairman of the National Health Council at the American Health Congress, Atlantic City, May 22; Dr. William F. Snow, New York, vice chairman; Dr. Linsly R. Williams, New York, treasurer; Dr. Ellice M. Alger, New York, recording secretary, and Dr. Thomas C. Edwards, New York, acting executive officer.——The Mid-Western Association of Anesthetists will hold its annual meeting, October 11-14, at Kansas City, Mo.; physicians or dentists desiring to present a paper at this meeting should communicate with the secretary, Dr. Ralph M. Waters, 425 Argyle Building, Kansas City, Mo.——The Mississippi Valley Sanatorium Association will hold its annual meeting in conjunction with the Mississippi Valley Conference on Tuberculosis at Chicago, June 15, at the John B. Murphy Memorial Building, 40 East Erie Street; at 12:30 there will be a luncheon at the Hotel Sherman given by the president, Anton J. Cermak, of the board of county commissioners——Dr. George M. MacKee was elected president of the American Dermatological Association at the meeting in Philadelphia, May 27-29; Dr. Otto H. Foerster, Milwaukee, vice president, and Dr. Clarence Guy Lane, 416 Marlboro Street, Boston 17, Mass., secretary-treasurer.

FOREIGN

Typhus at Medical College.—Six members of the staff of the Peking Union Medical College, Peking, China, had typhus fever or were convalescing, according to a newspaper report, May 29, contracted while caring for the Mukden troops outside the walls of the city. The epidemic of typhus in Peking, which resulted in 1,000 cases among civilians this year, has passed its peak.

Prizes for Research on Venereal Disease.—The French Ligue contre le péril vénérien offers a prize of 5,000 francs for the best work presented on heredosyphilitic psychopathies in children and adolescents, and their share in juvenile delinquencies. A similar prize will be given for the best work on the association of syphilis and tuberculosis in bone and joint disease. A further prize of 20,000 francs will be awarded to the one making the most important discovery in the field of venerology during 1926 and 1927. The headquarters of the league are at rue de Lisbonne 44, Paris. The competing works must be received before Oct. 1, 1928.

Cultist Sentenced for Involuntary Homicide.—The *Deutsche medizinische Wochenschrift* gives the details of the case already mentioned in The Journal in which the Lübeck courts condemned a Christian science practitioner to six months' imprisonment for manslaughter from neglect of due caution (*fahrlässige Tötung*). She had acceded to the request of the parents and proceeded to treat with prayer alone a boy, aged 14, who had fallen on a picket, which entered the abdomen. The supreme court in a decree, dated Oct. 5, 1925, confirmed the sentence, specifying that the cultist should have refused to take charge of the case and should have advised the family to call in a physician.

International Commission on Rheumatism.——The *Nederlandsch Tijdschrift voor Geneeskunde* relates that twelve countries sent representatives to the convention organized to discuss better methods for prevention and treatment of rheumatism, which was held recently at Prague. It was decided to found a central bureau, with headquarters in the Netherlands; Dr. J. van Breemen, Amsterdam, will probably be in charge. The important social-economic aspect of rheumatism is being studied with special interest now in England, Czechoslovakia, Austria and elsewhere, national committees having been organized for the purpose in ten countries.

Public Health in Jugoslavia.—From a letter in the *Deutsche medizinische Wochenschrift* we note that Jugoslavia in the last five years has founded 23 institutes for hygiene, 9 for epidemiology, 19 for bacteriology, 3 malaria stations with 42 branches, 50 venereal disease policlinics, 34 tuberculosis stations, 18 for trachoma, and other institutions, to a total of 250. In four years 22,480 persons were given preventive treatment for rabies. The Rockefeller Foundation donated twenty millions to the work, and the Health Commission of the League of Nations aided in the fight against malaria, which presents special problems owing to the peculiar conditions of the water supply. In 1924, 220,561 persons were examined for malaria, and 2,100 Kg. of quinine was distributed, colored to prevent resale. The progress of hygiene is handicapped by the lack of manuals in the language of the country, and reliance has to be mainly on moving pictures in education of the public.

Personal.—Dr. C. Richet, professor emeritus of physiology at the University of Paris, a pioneer in biology with anaphylaxis and serotherapy, was presented, May 22, with a bronze portrait bust and tributes from delegates of scientific societies throughout Europe. Belgium sent the insignia of the grand commander of the Order of Leopold, and General Foch presented him with the cross of the grand commander of the Legion of Honor.——Prof. R. Bastianelli was in charge of the reception tendered the Interstate Postgraduate Clinical Assembly of North American Physicians at the capitol at Rome.——Dr. Monod, Vichy, and Dr. Fox, London, presided at the International Congress on Medical Hydrology, held recently at Carlsbad.——Honorary citizenship was conferred on Prof. S. Freud by the city of Vienna on his seventieth birthday, May 6.——Dr. L. Bernard and ten other members of the Académie de médecine at Paris have been appointed a committee to organize a laboratory for the purpose of supervising the drugs obtainable by the public dispensaries and practitioners for the treatment of syphilis.——Prof. E. Kraepelin, Munich, has been awarded a fund for a five months' study in India of paralysis.——The triennial Manson medal has been conferred by the London Tropical Medicine Society on Prof. E. Marchiafava, Rome, for his works on malariology.——The seventieth birthday of Dr. Adolpho Lutz was celebrated recently in Brazil, as the pioneer of experimental medicine, parasitology and biology. He is still actively at work in the Instituto Oswaldo Cruz, where he has made many discoveries.——The Hungarian Academy of Science has given the academy prize this year to Dr. E. Krompecher, professor of pathology, University of Budapest, for his work on cancer.——The Académie des sciences morales at Paris has conferred the Audiffred prize on Dr. M. Ménard, radiologist of the Cochin hospital, crippled by injuries from the roentgen rays.

Deaths in Other Countries

Dr. **M. Pellissier**, Lille, professor of pathology, author of various medicolegal tests, aged 40.——Dr. **A. Barlocco**, Modena, professor of clinical medicine.——Dr. **C. Sforza**, Florence, formerly general medical inspector of the Italian army medical department, director of the *Giornale di Medicina Militare*, aged 78.——Dr. **E. Landolt**, Paris, whose works in all fields of ophthalmology are internationally known, one of the three founders of the *Archives d'ophtalmologie* in 1881, aged 79.——**Sir William Boog Leishman**, director-general, British Army Medical Service; honorary physician to the king; formerly president, Society of Tropical Medicine and Hygiene; for ten years member of the Medical Research Council; chairman, Foot and Mouth Disease Research Committee; late examiner in pathology at Oxford University and in tropical medicine at the University of Cambridge, June 2, following a short illness.——**William Frederick Shanks**, professor of physiology, University of Leeds, England, April 15, aged 38.——Prof. **F. v. Soxhlet**, emeritus professor of agricultural chemistry at Munich, inventor of an apparatus for sterilizing milk which bears his name, aged 79.——Major Le Goff, of the French medical corps, killed in an airplane accident while taking wounded to the hospital in Morocco.

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 29, 1926.

The Congress of Institute of Public Health

This year's congress of the Royal Institute of Public Health is to be held at Bristol, from May 19 to 24, inclusive. Tuberculosis and cancer problems are among the topics that will engage the attention of the Section of State Medicine and Municipal Hygiene. The Duchess of Hamilton is to open a discussion on "Humane Slaughtering." A contribution of general interest should be that on "How to Get a Smokeless Atmosphere—and Make It Pay," by Councilor W. Brownhill Smith, chairman of the Glasgow Health Committee. The discussion in the Section of Naval, Military, Air and Tropical Diseases of Health Questions, having special reference to the services, is to be supplemented by several papers of great general importance; for instance, that on "The Relative Connection Between Chemical Warfare, Physics, Chemistry, Meteorology and Public Health," by Major H. S. Blackmore. Many phases of health in reference to the factory and workshop are to be debated before the Section of Industrial Hygiene. "Vocational Selection" is the subject of three of the contributions. The president of the Section of Pathology, Bacteriology and Biochemistry is Dr. J. C. Adami. He will open a discussion on cancer in a session jointly with the Section of State Medicine and Municipal Hygiene. The Section of Women and the Public Health is to be presided over by the Duchess of Beaufort. Papers and debates on various subjects related to the welfare of children and of women engaged in industry will figure in this department. "The Psychology of Women Workers" is to be dealt with by Miss May Smith and Miss Sheila Barington.

The Nervous System of Plants

Sir Jagadish Chandra Bose, F.R.S., the Indian biologist, lecturing at University College, controverted the views of Pfeffer and others that a hydromechanical disturbance or the secretion of an irritant by a wound is necessary for excitation in plants. He said that an excitatory impulse was generated in the plant by a feeble stimulus which caused no wound or any physical disturbance. He found that *Mimosa pudica* could be excited by an electric shock one tenth of the intensity that evoked human sensation. By such a feeble stimulus, which caused no wound and no mechanical disturbance, the plant could be uniformly excited time after time, and the velocity of its nervous impulse determined under normal or changed external conditions. The impulse was transmitted not only upward but also downward against the direction of the movement of sap. Cold applied on the path of conduction slowed down and arrested the impulse; narcotics produced a temporary stoppage, and poisons permanently abolished it. He had been able to produce an artificial paralysis in the plant nerve, which was cured by applying the same treatment found effective in the removal of paralysis in the animal. Bose gave demonstrations by means of his "resonant recorder," whereby the plant automatically inscribes the speed of its nervous impulse. He had found the perception or latent period of the motor organ of *Mimosa* to be six one-hundredths second. Fatigue prolonged the latent period; when excessively tired, the plant lost its power of perception, which was regained only after half an hour's absolute rest. In stout specimens the speed of reaction was sluggish, whereas a very thin specimen attained its acme of excitation in a very short time. A plant protected under glass from the stimulating buffets of the elements looked sleek and flourishing, yet in reality it was flabby, its nervous power remaining undeveloped. But when a succession of blows fell on this effete specimen, the shock created nervous paths and wakened it up into activity. Bose had been able to localize the plant nerve by two independent methods: first, by the electric probe; and, secondly, by selective staining. He had discovered a highly active and rapidly oxidizable substance in the quickly contractile pulvinus of *Mimosa*, whereas it was absent in the inactive and insensitive pulvinus of the ordinary bean plant. In the leaf stalk of *Mimosa*, four nerves led from the four subpetioles to the four quadrants of the pulvinus, each of which had a distinct motor function. If one of the four subpetioles was stimulated, a definite impulse was sent along the particular nerve to stimulate its own quadrant. But energy was conserved at the center, and the outlying organs were quickly adjusted to meet any crisis. But one advantage secured by such a highly elaborated nervous system was the coordinated reflex by which the leaf surface was adjusted perpendicularly to the incident light, so as to insure the largest amount of radiant energy for photosynthesis. Another important function was the transmission of a rapid message to the motor organ for quick reaction in avoiding threatened danger. Large patches of ground in the tropics are covered by *Mimosa*. When one of the vivid green leaves is trampled on or bitten by grazing cattle, a nervous impulse is sent through the plant, the leaves fall and press themselves against the ground, and the leaflets also close. A patch of vivid green is rapidly transformed into thin lines of dull gray unnoticed against the dark ground. The plant thus saves itself literally by "lying low" and making itself invisible.

Birth Control Discussed in the House of Lords

In the house of lords, Lord Buckmaster moved that the government be requested to withdraw all conditions imposed on welfare committees for the purpose of causing the withholding from married women of information when sought as to the best means of limiting their families. The control of birth was, he said, being extensively practiced by the well-to-do, and it was only among the poorest and the most ignorant that this knowledge had not permeated. In 1,000 married people under the age of 50, the birth rate for schoolmasters was 93; for clergymen of the Church of England, 100; for clergy of all denominations, about 102; for physicians and professional men, from 103 to 105; for skilled laborers, 153, and for unskilled laborers, 247. The standard of intelligence measured in the same way by examination of the children in the schools showed a decreasing scale of intelligence, which was in the exact inverse ratio to this standard of birth rate. The ministry of health provided money to assist welfare centers set up by local authorities, and to enable help and advice to be given to women expecting children, and to women who had young children. But an express prohibition prevented the information from being given as to the means by which future births might be prevented. Should that state of things, not merely in the interests of justice but in the interests of the race, be allowed to continue? Many people deplored the fact that birth control was exercised by the well-to-do, but it was no use weeping over lost battlefields. The reason was this: It was not, as some said, that women were selfish and men were worthless and sought nothing but pleasure, but it was a much higher thing—the increased respect for the sanctity of life, and the desire of people to see that their children were not pressed out by the illimitable competition of unrestricted numbers. It was inspired by the hope that parents would be able to make for their children a better place in the world than they themselves once filled. The better and more thoughtful people were limiting their children, and the sickly, the diseased and the underfed were reproducing at a rate nearly double that of anybody else. He asked that duly qualified physicians should not have their discretion fettered in giving advice. The idea that economically, under all circumstances, the population ought to be reproduced was long since dead. Children were no longer to be treated as fodder for the production of big profits in the balance sheets of manufacturers. With regard to the argument that limitation of the birth rate meant descending in the scale of nations, he asked whether nations were to be tested by their fecundity, like rabbits. It was not numbers that would win the next war, but brains. As to the deep-rooted religious objection as to limitation, he was unable to understand its grounds. It was said that the right course was for men and women to exercise self-restraint, and that abstention would solve the difficulty. The doctrine of abstention was a mischievous doctrine and would lead to the shattering of more homes than any of the causes they had heard denounced in that house.

For the government, the Marquess of Salisbury said that he approached the subject with great diffidence. In trying to remedy the sorrows with which they sympathized, they must be careful that they did not strike a vital blow at a work of service which was doing infinite good to the poorest class. Lord Buckmaster would strike a fatal blow at the maternity and child welfare movement. He was proposing to introduce into its purview a subject that was alien and in the highest degree controversial. Birth control might be useful and necessary, but the kind of people interested in the one movement were not necessarily interested in the other. It would profoundly shock a large number of those engaged in the voluntary work at child welfare and maternity centers if birth control were brought within their purview. The feeling on this subject was not confined to the Roman Catholic Church. It was shared by a large number of religious bodies. Supposing a large number of these voluntary workers who agreed with the Roman Catholic Church or with other churches on this matter should resign their work at the child welfare and maternity centers, what would become of this highly successful movement? For these reasons the government could not support the motion. Birth control was not confined to people whose health dictated that they should not bear more children. It was largely supported by women who probably could have children but preferred not to have, women who preferred their own ease.

In the discussion that followed, the lord chancellor pointed out that the house was not asked to express any opinion for or against birth control, or to say whether propaganda in favor of birth control should or should not be lawful. The resolution was not confined to women who sought advice on the ground of health: it extended the right to information to all married women. Moreover, it would empower a nonmedical member of the committee to give advice. The ministry of health intended that in any case in which it appeared to the committee that further conception might be dangerous to health, the person should be referred to the physician attached to the welfare center. The advice must be medical. Lord Buckmaster then said that there was a misapprehension as to the purpose of the motion. It was never his intention that information should be disseminated broadcast through unqualified people. The government did not object to the motion if he would only introduce the words "through the medical officer." He was quite willing to do so, but it was clear from the trend of the debate that the motion was opposed not on this ground, but on the ground that the information ought not to be distributed at all. He was perfectly willing that there should be medical control, but he was not willing that a physician should be put in charge of one of the most delicate and important medical subjects and that then his discretion should be fettered. The motion was carried by 57 votes to 44.

Fibrous Pulmonary Tuberculosis

In a clinical lecture delivered at the University of Strasbourg, Prof. Dumarest stated that fibrous pulmonary tuberculosis was common and almost invariably overlooked by the physician, the diagnosis being made only by radiology. Fibrous tuberculosis is benign rather than curable, but it may remain quiescent for a long time. Pregnancy does not influence it, while its treatment is the same as in other forms of pulmonary tuberculosis.

Marienbad

The high court of justice in Prague has just published its decision on the future control of the mineral springs at Marienbad. As is well known, the Czechoslovak land office, in its redistribution of land by the seizure and breaking up of large estates, encountered strong opposition from the German monastery at Tepl, to which all the mineral springs and much property of this watering place belong. The decision reached is a compromise, which leaves certain property, including the Central Bath and Central Park, in the hands of the monastery, while the Kreuzbrunnen and the Rudolph and Ferdinand springs will be taken over by the state.

Sex Determination

Some work on the determining causes of sex is being done by Dr. E. Trottet at Bern. Experiments undertaken to date to influence sex may be divided into five categories, not always well defined: (1) surgical means, as Trottet's work in unilateral castration; (2) physical means, by influence of heat or light; (3) chemical means, such as injections of alcohol; (4) physiologic means, such as increased or decreased nutrition of the ovum; (5) means which are called chemicophysical on account of their peculiar action, such as epinephrine, choline and lecithin. Trottet's experiments with epinephrine may be termed chemicophysiologic. One of these resulted in extremely interesting data. Injections given during the first fifteen days of intra-uterine life in a rabbit gave a surplus of more than 20 per cent of males over females. More remarkable still is that of twenty-five litters, twenty-one had males in the majority; in two, females predominated, and in two the number of males and females was equal. Comparing these results with other experiments, it is evident that the effects of epinephrine manifest themselves between the tenth and fifteenth days of intra-uterine life. Egli and Coert's experiments show that differentiation of the sexes begins, in the rabbit, on the twelfth day and is marked between the fifteenth and eighteenth days. Kowalesky's experiments show that the favorable moment for influencing the sex is extremely short. In the guinea-pig it is between the fourteenth and fifteenth day of gestation; in the rabbit, epinephrine has no influence during the first five days of gestation. Trottet says that these conclusions are correct and he is able also to state that epinephrine is without action during the first ten days of intra-uterine life. The most favorable moment for influencing the sex with epinephrine in mammals is the moment when the genital glands begin to differentiate themselves.

Epinephrine is vasoconstrictive, especially on vessels of small caliber, and it is a question whether or not it is this property which exercises its influence on the development of the sex. Trottet believes that it is. Apert's experiments tend to prove that epinephrine influences the sex in favor of males, while Kowalesky's conclusion is that sex is determined by the oxygen content of the embryo's food. Food rich in oxygen produces females, while a low oxygen content produces males. Following an injection of epinephrine there is considerable vasoconstriction of the minute vessels, and hence a reduction of the placental circulation as well as that of the fetus. Although the maximum duration of the action of epinephrine is four hours, according to Trottet, it may be that by its vasoconstrictive action epinephrine causes defective placental blood circulation, and the resulting reduction of the oxygen supply hinders the development of the female genital organs. Hence Trottet and Kowalesky are in accord, although they arrive at their conclusions by very different routes.

May 2, 1926.

Unveiling of Cajal's Statue

In El Retiro, the historic and most beautiful park of Madrid, a monument by the sculptor Victorio Macho has just been erected to Cajal. Macho has shown originality. A pond fed by the Spring of Life and the Spring of Death lies before a wall, which opens in the center to make room for a statue of Wisdom. Cajal's statue overlooks the water. The head especially is an excellent likeness. The king, the premier, all learned societies and government officials attended the unveiling, as well as a large crowd of students and admirers of Cajal as a scientist.

The New Public Health School

The development of the Alfonso XIII Immunology and Serotherapy Institute and the new King's Hospital for Infectious Diseases paved the way for the organization of the National Public Health School. The king again attended the dedication. Dr. Murillo, the director general of public health, pointed out the sanitary advances made in Spain during the last decades. The Public Health Service has a modern set of regulations, a force of provincial sanitary inspectors, a complete port and border quarantine system, sanitary brigades, venereal dispensaries, an antimalarial and antituberculosis organization, a number of tuberculosis sanatoriums, a child welfare institute and a drug control institute. The death rate has decreased from 29 per thousand in 1900 to 19 in 1924, meaning a reduction of 10 in the present century.

The National Public Health School will train the regular sanitary corps. In addition, it offers special courses for auxiliary and subordinate employees, such as nurses and disinfectors. Graduate teaching for physicians, engineers, architects, veterinarians and chemists, also is offered. Dr. Murillo favors specialization in health matters, but on a medical basis. "I cannot approve," he said, "a tendency born in America and introduced in some schools there, namely, the creation of a sanitary profession separate from the medical career. Without an anatomic and clinical background, it is impossible to understand disease or master prevention. Anything else leads to empiricism. This school will be guided by medical thought, and its teachers and executive officers will be physicians, although the aid of other professions will be solicited. In Spain as elsewhere, physicians will eventually make their choice between giving their full time to public health or to private practice."

A Gold Medal to Dr. Pulido Fernández

The Physicians' Society of Madrid has bestowed a gold medal on Dr. Pulido Fernández, perpetual secretary of the National Academy of Medicine. Dr. Bauer, the president of the society, reviewed Dr. Pulido's efforts on behalf of the insane, the sick, the blind, children and especially the work which has popularized Pulido's name abroad, his endeavors to reestablish old ties with the descendants of the Jews who were expelled from Spain by the Catholic kings and still speak Spanish.

Medical Matters in Argentina

Dr. Slocker, chief surgeon of the Rubín Institute, has delivered a lecture at the National Academy of Medicine on his recent trip to Argentina.

Recent hospital enlargement has increased the number of available beds in the city hospitals from 5,000 to 12,000. In addition, there are about 3,000 beds in the Spanish, Italian and other foreign hospitals. The Rawson Hospital was practically rebuilt as a whole. In the Clinical Hospital, Dr. Arce has converted his service into a surgical institute, using the 4,000,000 pesos (about $1,600,000) and 700,000 pesos (about $280,000) appropriated for the installation and maintenance, respectively, which he secured during his tenure as president of the university and member of congress.

A number of Spanish physicians have recently given lectures in the Buenos Aires medical school. Among them is Dr. Río Ortega, discoverer of the microglia, whose technic is now generally used there. The anatomic institute was created by a Spaniard, Dr. Avelino Guitérrez, who has also organized the Cajal chair. This will be occupied every year by a prominent Spanish scientist. Another Spanish professor, Dr. Pedro Ara, was engaged for three years as professor of anatomy in the Cordoba University, as the Argentinians found the specimens he exhibited at the Seville Medical Congress superior to any they had seen in either Europe or America. Medical research seems to be developing unusually well, as the munificent salaries paid attract competent workers.

Argentine physicians occupy in politics a well deserved prominence, which they turn to account to secure proper appropriations for hospitals and health purposes. Foreign physicians, including Spanish, must take a full series of examinations, spread through a four year period, and pay 3,000 pesos (about $1,200) for dues. Only in one province (Cordoba) are foreign physicians allowed to practice, pending their licensing. In unhealthful districts, such as Tucumán, foreign physicians are allowed to practice, but at a salary, and can accept no private fees.

In Argentina, no foreign professional men are needed, as their school can fill all demands. Practically every medical position in the Spanish societies and institutions is filled by Argentinians, mostly of Spanish extraction. A few years ago, an attempt was made to establish reciprocity agreements among the several South American republics and Spain, but Argentina, Chile and Uruguay demurred. Dr. Slocker pleaded for a modus vivendi, granting Spanish physicians who have resided at least five years in Argentina the same rights enjoyed by Argentine physicians trained abroad, or authorizing them to practice in towns under 5,000 inhabitants, and anywhere, provided they have been employed by the government more than five years.

VIENNA

May 12, 1926.

The Seventieth Birthday of Professor Freud

As the seventieth birthday of Siegmund Freud, the founder of psychanalysis, approached, his friends and pupils arranged for special ceremonies, although it was evident that the central figure would gladly have dispensed with display. Freud has spent his whole life in Vienna. He had to pass through the usual struggle with the forces of misunderstanding, ignorance and malice before he came to be recognized, and his doctrines were accorded full honors in foreign countries before they were accepted at home. In 1895, he published in collaboration with Dr. Breuer a small treatise entitled "Studies on Hysteria," which contained an exposition of the fundamental principles of psychanalysis, as demonstrated on a female patient. Freud showed in that treatise that, in the manifestations of hysteria, forgotten, or at least suppressed, conceptions or ideas played a predominant part. In his "Dream Interpretation," which appeared in 1900, he showed that "the subconscious mind" determines all our thoughts, acts and expressions of instinctive impulses. That demonstration opened up the way to an understanding of the normal psychic life and made clear also the manifestations of the pathologic psychic life. The treatises on "Witz und Unbewusstes," "Massenpsychologie," "Das Ich und das Es," and "Jenseits des Lustprincips," mark the milestones in the development of the system. The Psychanalytic Society, founded by Freud, is closely associated with allied societies in Germany, France, England, Italy and Spain. This organization has helped to demonstrate to the medical profession the significance of sex in the psychic life, just as researches on symbolism and perversion have furnished an insight into the problems of neurosis. On Freud's seventieth birthday, all the newspapers of the city, at the request of their readers, published popular articles on the nature and methods of psychanalysis.

Celebration in Honor of Professor Eiselsberg

Prof. A. Eiselsberg, Billroth's greatest pupil, has held the position of head of the First Surgical Clinic in Vienna for a period of twenty-five years, in honor of which anniversary a special celebration was held. Professor Clairmont of Zurich, Professor Marburg of Vienna, and Professor Sauerbruch of Munich emphasized the great importance of Eiselsberg as teacher, investigator and man. A number of special publications in commemoration of the day and which dealt with Eiselsberg's work were presented to him.

The Odor Emanating from the Sick

In an article in the daily press, Dr. Valentus discusses the fact that the physicians of antiquity—and also careful observers among modern physicians—were able to reach diagnosis through their sense of smell. Professor Chvostek, among others, has stressed the fact that the sense of smell should play a dominant part at the bedside. The odors of acetone in severe diabetes, of ulcerating carcinoma of the rectum or of the breast, and of cancer of the larynx or of the tongue, are well known. Many physicians know the odor of a gumma of the nose, which resembles the fetor of ozena. Many laymen are familiar with the odor of ozena. Experienced practitioners call attention to an odor given off by typhoid patients, which is, however, not always noticeable. Icterus patients have an unpleasant, easily recognized odor about them, while a room full of scarlet fever patients smells like the cages of wild animals. Hyperhidrosis pedum as well as other marked sweat secretions have a well known odor, but not many are aware that tuberculous persons give off a peculiar odor. The odors of carious teeth, of suppurating bone injuries, or of ulcus cruris are known to many. Especially, during the war, the odor of pus was familiar to all who frequented the surgical hospitals. The fetid sputum in many forms of lung disease (gangrene, bronchiectasis), and the odor of gangrenous wounds or of cholesteatoma of the ear are diagnostic. If, as Chvostek demands, one begins at the outset of medical study to note peculiar odors, much information may be secured through the nose.

Trichinosis, Rabies, Glanders and Influenza in Austria

Reports of the public health service show that, in the last covered. The origin of the infection lay in a shipment of six months, in Vienna, a few cases of trichinosis were dissmuggled pork. The outbreak of glanders was confined chiefly to a rural district in the eastern provinces of the republic. There were seven cases, five of which ended fatally. In all cases the diagnosis was reached late, but the original focus was eliminated. There has been a considerable increase of rabies. For some unascertained reason, the control of hydrophobic animals has been lax of late. As a result, several persons have died, in spite of the fact that Pasteur treatment was administered soon. Not dogs but other domestic animals have been the offenders. There has been an epidemic of mild influenza in Austria since the middle of February. It appears either as an inflammation of the upper respiratory passages, or as "gastro-intestinal" influenza. Ear complications are common, especially in young children, but they heal quickly.

May 1, 1926.

Congress of Internal Medicine

At the annual session of the Deutsche Gesellschaft für innere Medizin, held in Wiesbaden, April 12-15 (The Journal, May 29 and June 5, pp. 1710 and 1782), the principal paper on the third topic, the pathology and therapy of asthma, was presented by Professor Klewitz, chief physician at the Medizinische Universitäts-Klinik in Königsberg.

We do not know for a certainty how an attack of asthma is brought about. It is probable that the cause is a spasm in the muscle layers of the bronchi, which may be produced in animals by the same substances which in man may bring on an attack. The spasm contracts the lumen of the bronchi, and the effect is still further increased by viscous secretions and congestion of the mucous membranes. The expiration period is lengthened, and the rhythm of breathing undergoes disturbances. We must distinguish two groups of patients. By far the majority are hypersensitve to definite substances. Such hypersensitiveness may, through transference of blood, be artifically transmitted from man to man or from man to animals. The number of substances that may produce an attack of asthma is extremely large. Among others are articles of food, substances produced by animals, chemicals, parasites, and, finally, unknown atmospheric factors, which are referable, for the most part, to plants, parasites or animals. In all these manifestations, inborn constitutional factors exert a predominant influence. In the second main group of asthma patients, hypersensitiveness plays no part. Here we have to do with disturbances of the autonomic nervous system, which is not subject to the will, but which reacts to slight psychic, chemical or physical irritants by a spasm of the bronchial muscles and a stimulation of secretions. With that is associated a functional weakness of the respiratory processes controlled by the central nervous system. The diagnosis seeks to establish the injurious substance which in the first group is the cause of the attack. The treatment consists in keeping the patient away from the things that precipitate an attack. This becomes difficult when several different foods are known to bring on the attack. Often a change of occupation becomes necessary. Of late years, attempts have been made gradually to desensitize hypersensitive persons by cautious injections of extracts of the injurious substances, but the results have not been satisfactory. Better results may be secured by nonspecific injections (peptone, tuberculin, sulphur, milk). Roentgen-ray treatment may accomplish a complete cure. In an acute attack, the most reliable remedy is epinephrine. Attempts have been made, also, in late years, to cure asthma by the operative removal of the sympathetic nerve in the neck.

During the discussion, Professor Storm of the Netherlands said that most asthma patients who are hypersensitive to any substances whatever react to injections of an extract of human dandruff, to which normal persons do not react. In high plateau regions, asthma patients are usually free from attacks. Storm ascribed this to the absence of irritating substances in the atmosphere of elevated regions. In chambers to which air had been conducted from the upper air regions, 75 per cent of the hypersensitive patients remained free from attacks. In these 75 per cent, substances floating in the air are the cause of the disease, and only in from 5 to 8 per cent is the causative factor animal hairs or food. The injurious substances in many homes are animal or vegetable parasites.

Veil of Munich observed an ionic activity in asthma which could be influenced by psychic treatment and which was the expression of a universal disturbance of the function of the vegetative nervous system. Localization in certain brain centers has been shown. Berger of Innsbruck rarely noted in hay-fever a utilizable cutaneous reaction, but occasionally secured good results from desensitization. Hofbauer of Vienna observed disturbances of nasal breathing before an asthmatic attack. He sought to reproduce these conditions in animals. Kammerer of Munich secured relatively frequent reactions with extracts he prepared himself; intracutaneous inoculation with dandruff extract effected desensitization. Leschke of Berlin found in only 10 per cent of the cases that asthma was occasioned by foodstuffs or animal hairs. A large majority of patients are hypersensitive to room dust and to infectious particles floating in the air. An allergen-free room can be dispensed with provided all rooms, and especially the sleeping room, are kept scrupulously free from dust. Asthma is related to disturbance in the midbrain, and is identical with anaphylaxis. In cases of food allergy, a test diet with zwieback, tea, sugar and red wine is recommended. Curschmann of Rostock stressed the psychogenic factor and the constitutional disposition. Calcium therapy and prophylaxis are effective, and also roentgen-ray treatment. In using epinephrine, attention should be paid to possible injuries of the aorta. Laudenheimer of Munich secured in numerous cases successful results with hypnosis, but at the same time breathing exercises were instituted. Psychic traumas were frequently noted in allergic asthma. Stöhelin of Basel expressed the view that also in allergic asthma there is always a nervous component. The treatment must therefore take account of both factors. Erich Meyer of Göttingen recognizes allergic patients by the increase of the serum globulins after the injection of protein and reinjection. Gigon of Basel observed that hypnosis may have an influence on the changes of metabolism. Krehl of Heidelberg pointed out that allergy and psychic influences interact. His of Berlin reported several cases that were allergic to various "tests." Many types could be influenced favorably by spasmolytic agents. Asthma must be viewed quite differently if it is a complication of chronic bronchitis. Attacks in children that do not yield to ordinary treatment are subject to psychic influence.

Wiesbaden's New Institute for Scientific Research in Balneology and Metabolism

The city of Wiesbaden has appropriated 100,000 marks for the erection and equipment and 50,000 marks annually for the support of an institute for scientific research in balneology and metabolism.

Marriages

Richard Gilmore Coblentz, Baltimore, to Miss Mary Knight Compton of Montgomery, Ala., May 22.

Clarence Hayes Glover to Miss Alma Belle Osteen, both of Memphis, Tenn., March 17.

John H. Donovan to Miss Besse Evans, both of Windsor, Ill., May 3.

Deaths

Herbert Nathan Thomas Nichols ⊕ Ahmeek, Mich.; Medical Department of the Tulane University of Louisiana, New Orleans, 1913; formerly assistant in anatomy at his alma mater; at one time government physician among the Eskimos, U. S. Bureau of Education; assistant physician to the Mohawk Mining Company since 1922; aged 47; died, April 5, at Calumet, of septicemia.

Alvord Gates Nichols, Boston; Medical School of Harvard University, Boston, 1922; member of the Massachusetts Medical Society; formerly on the staff of the Peter Bent Brigham Hospital; assistant medical director of the John Hancock Mutual Life Insurance Company; aged 32; died, May 18, of pylephlebitis following an abscess of the appendix.

Frank Paul Summa, Nanticoke, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1913; member of the Medical Society of the State of Pennsylvania; served during the World War; member and past president of the board of education; aged 38; died suddenly, May 13, of heart disease.

William Hilliard Cryer ⊕ Birmingham, Ala.; Medical Department of the Tulane University of Louisiana, New Orleans, 1908; member of the New Mexico Medical Society; medical director and superintendent of the Jefferson Tuberculosis Sanatorium; aged 42; died, April 27, of uremia.

Charles Philadelphus Cathcart, Kansas City, Mo.; Eclectic Medical Institute, Cincinnati, 1872; University Medical College of Kansas City, 1884; member of the Missouri State Medical Association; aged 76; died, April 20, at the Christian Church Hospital, of pernicious anemia.

Arthur Parker Lewis ⊕ Reno, Nev.; College of Physicians and Surgeons of San Francisco, 1900; Spanish-American War veteran; on the staff of the Reno Hospital; aged 51; died, May 26, following an appendectomy, tonsillectomy and the extraction of a tooth.

Ellsworth Orton ⊕ Pontiac, Mich.; Detroit College of Medicine and Surgery, 1892; formerly mayor, city health officer and county physician; aged 60; died, May 17, at the Harper Hospital, of sepsis, following an infection of the throat.

William A. Emens, Trinity, Ala.; Hospital College of Medicine, Medical Department Central University of Kentucky, Louisville, 1905; member of the Medical Association of the State of Alabama; aged 47; died, April 25, of pneumonia.

Henry B. Lee, Summerville, S. C.; Medical College of the State of South Carolina, Charleston, 1871; for several years member of the state legislature; Spanish-American war veteran; aged 76; died, May 20, of cerebral hemorrhage.

Willet Patterson Hughes ⊕ Bloomsburg, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1897; served during the World War; aged 55; died, April 26, at a hospital in Danville, of ruptured aorta caused by a fall.

Maurice A. Hansen, Osage, Iowa; Central College of Physicians and Surgeons, Indianapolis, 1898; member of the Iowa State Medical Society; aged 52; died, at a hospital in Rochester, Minn., May 10, of intestinal obstruction.

Cyril Gustavus Devron ⊕ Lakeland, La.; Medical Department of the Tulane University of Louisiana, New Orleans, 1923; aged 26; died, May 4, at the Lady of the Lake Sanitorium, Baton Rouge, of bronchopneumonia.

Morgan Frederick Mount, Hot Springs National Park, Ark.; Hahnemann Medical College and Hospital of Philadelphia, 1903; member of the Arkansas Medical Society; aged 55; died, May 1, at a local hospital.

Harold Charles Golly ⊕ Utica, N. Y.; Jefferson Medical College of Philadelphia, 1917; served during the World War; on the staffs of St. Elizabeth's and St. Luke's hospitals; aged 32; died, April 20, of heart disease.

George Pierrard Bertholet ⊕ Pawtucket, R. I.; University of Montreal Medical Faculty, Montreal, Que., Canada, 1911; served during the World War; aged 38; died, April 21, of myocarditis and acute nephritis.

Niceus Walker Mayginnes, Tulsa, Okla.; University Medical College of Kansas City, 1884; member of the Oklahoma State Medical Association; aged 70; died, May 20, at a sanatorium in Kansas City.

Hollis F. Sigler ⊕ Pinckney, Mich.; University of Michigan Medical School, Ann Arbor, 1877; past president of the Livingston County Medical Society; aged 72; died, May 10, of cardiovascular disease.

George J. Mahr, Brooklyn; Medical Department of the University of the City of New York, 1895; member of the Medical Society of the State of New York; aged 55; died, May 23, of heart disease.

Isaac Napoleon Porter, New Haven, Conn.; Yale University School of Medicine, New Haven, 1893; member of the Connecticut State Medical Society; aged 61; died, April 10, of cerebral hemorrhage.

Alexander M. Wallingford ⊕ Flemingsburg, Ky.; University of Louisville School of Medicine, 1890; aged 57; died, May 9, at a hospital in Lexington, following an operation on the gallbladder.

Albert Blackburn Prewitt, Carlisle, Ky.; Louisville National Medical College, Medical Department State University, 1896; aged 58; died, May 8, of paraplegia following a long illness.

Edward Lafayette Sperry, Potter Valley, Calif.; Starling Medical College, Columbus, 1881, and Jefferson Medical College of Philadelphia, 1882; aged 69; died, March 31, at Monrovia.

Isaiah E. Hamilton ⊕ Lawton, Mich.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1887; Rush Medical College, Chicago, 1894; aged 62; died, May 12, of heart disease.

Cecil Carl Burnett, South Solon, Ohio; Ohio State University College of Medicine, Columbus, 1916; aged 39; died, May 13, at Columbus, following an operation for gallstones.

Horace Maynard Taylor, Greeneville, Tenn.; University of Tennessee College of Medicine, Memphis, 1901; aged 51; died, May 11, of pneumonia following a cholecystectomy.

Ralph Denniston Dean ⊕ Taunton, Mass.; Medical School of Harvard University, Boston, 1896; on the staff of the Morton Hospital; aged 53; died, May 11, of leukemia.

Franklin K. Berry, Philadelphia, Tenn.; Jefferson Medical College of Philadelphia, 1867; Civil War veteran; aged 84; died, March 20, at Sweetwater, of diabetes mellitus.

Henry Heilemann, Philadelphia; Jefferson Medical College of Philadelphia, 1893; veteran of the Spanish-American and World wars; aged 61; died, May 22, of heart disease.

Louis J. Lautenbach, Crystal Beach, Fla.; University of Pennsylvania School of Medicine, Philadelphia, 1881; aged 65; died, May 19, at Philadelphia, of angina pectoris.

Purvis S. Willson, Owosso, Mich.; Detroit College of Medicine and Surgery, 1893; for six years member of the Owosso School Board; aged 57; died, May 10.

William E. White, Burlington, Wis.; Milwaukee Medical College, 1897; member of the State Medical Society of Wisconsin; aged 64; died, May 9, of carcinoma.

Mary Clagett Cornell, Chicago; Hahnemann Medical College and Hospital, Chicago, 1901; aged 61; died, May 12, of bronchopneumonia and chronic myocarditis.

David F. Hanna, Gallatin, Mo.; Medical College of Virginia, Richmond, 1875; member of the Missouri State Medical Association; aged 74; died, May 13.

George Hill Carter, Lenoir, N. C.; Medical Department of the University of the City of New York, 1877; aged 70; died, April 19, of cerebral hemorrhage.

Percy Thomas Henry Wythe, Hamilton, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1920; aged 29; died, April 20.

Richard I. Vines, Longville, La.; Memphis Hospital Medical College, 1909; aged 52; died, April 12, of carcinoma of the stomach.

Charles Alexander Page, Oakville, Ont., Canada; Trinity Medical College, Toronto, 1898; aged 50; died, March 19, of pneumonia.

William Carroll ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1863; aged 91; died, May 3, of hypostatic pneumonia.

Donald Johnson, Marion, Mich.; Trinity Medical College, Toronto, Ont., Canada, 1891; aged 63; died, May 4, of pneumonia.

William H. Hayes, Springfield, Mo.; Cleveland Medical College, 1860; aged 89; died, March 31, following a long illness.

Frank W. Diemer, Springfield, Mo.; Missouri Medical College, St. Louis, 1891; aged 58; died, May 11, of nephritis.

Robert M. Sproul, Lima, Ohio; Medical College of Ohio, Cincinnati, 1880; aged 79; died, May 12, of heart disease.

Frank Eugene Baldwin, Peoria, Ill.; Rush Medical College, Chicago, 1897; aged 51; died, May 16, of pneumonia.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

ALLONAL NOT ACCEPTABLE FOR N. N. R.

Report of the Council on Pharmacy and Chemistry

Allonal is a preparation containing a combination of allylisopropylbarbituric acid and amidopyrine mixed with free allylisopropylbarbituric acid and an excess of amidopyrine. The combination between allylisopropylbarbituric acid and amidopyrine is readily decomposed into its components, and the firm's claims are based on the assumption that Allonal contains these two ingredients. The claim is made that allylisopropylbarbituric acid, "the new and distinctive component," possesses a greater hypnotic power than any of the other well known hypnotics of the barbituric acid series, but that it is relatively less toxic. The Council finds that the evidence cited by the firm does not substantiate this claim, and concludes that Allonal must be considered as the result of an effort to combine in one preparation the hypnotic properties of a member of the barbituric acid series and the analgesic properties of amidopyrine. The firm publishes long lists of conditions said to have been relieved by this combination, the only individualization being the recommendation of "1 to 2 tablets" for some and of "2 to 4 tablets" for others. In none of the clinical reports submitted by the firm does the author refer to observations in which either component of the drug was used separately or in which the relative proportion was varied: the Council holds that the absence of such data deprives these reports of much of their value as arguments for the use of Allonal. The new hypnotic, allylisopropylbarbituric acid, for which great superiority is claimed, is thus made available to physicians only in fixed combination with an antipyretic and analgesic drug which may not be needed and which in itself frequently causes untoward symptoms. The Council finds Allonal unacceptable for New and Nonofficial Remedies because of unwarranted therapeutic claims, nondescriptive name, and lack of satisfactory evidence that the administration of a mixture of allylisopropylbarbituric acid and amidopyrine in fixed proportions is rational, and has authorized publication of the following report.

W. A. PUCKNER, Secretary.

Allonal was introduced by the Hoffmann-LaRoche Chemical Works, New York, with the claim that it was a new synthetic compound of allylisopropylbarbituric acid and phenyldimethyldimethylaminopyrazolon (amidopyrine) made by fusing together the two components. Subsequently it was shown that Allonal was not a definite chemical compound; evidence was submitted by the firm, however, favoring the existence in Allonal of a combination of allylisopropylbarbituric acid and amidopyrine (in different ratio than originally claimed) mixed with free allylisopropylbarbituric acid and an excess of amidopyrine; as in the case of other salts of weak acids and weak bases, the presence of water or dilute acid resolves the weak combination into its components.

The A. M. A. Chemical Laboratory has reported that the amount of allylisopropylbarbituric acid and amidopyrine in Allonal Tablets (as sold on the market) is not in molecular ratio of 1 to 2, but contains an unequivalent amount of ingredients. Whether Allonal actually contains a molecular compound of allylisopropylbarbituric acid and amidopyrine is of little moment since, even if the compound does exist, it breaks down easily in water or 0.2 per cent hydrochloric acid and acts as a mixture. Moreover, the claims are all based on the assumption that Allonal contains these two ingredients.

The Hoffmann-LaRoche firm stated that allylisopropylbarbituric acid is "the new and distinctive component" of Allonal and that it "possesses a greater hypnotic power" than any of the other well known hypnotics of the barbituric acid series but is relatively less toxic. This and similar statements seemed to imply that although the hypnotic action had been increased by the substitution of certain groups in barbital, the toxicity had not been correspondingly increased. Previous attempts to secure derivatives of barbituric acid of this character having failed, the Council asked for evidence that this had been achieved in the case of allylisopropylbarbituric acid. The firm referred the Council to one paper by Wiki, a paper by Pohl and to two papers by Redonnet as stating that this compound "possesses the same hypnotic action, as, for instance, di-allylbarbituric acid but is distinctly less toxic." Pohl (*Ztschr. f. d. ges. exper. Med.* **38**:520, 1923) reports one experiment (rabbit) in which 0.058 Gm. of allylisopropylbarbituric acid per kilogram given *subcutaneously* caused deep narcosis for eight hours with a fall of temperature of 6.8 degrees; a similar dose of "Dial" caused narcosis of shorter duration. Pohl adds *"Nach Castaldi (Therap. Monatsh.* 1915, p. 54 [should be 454]) *ist Dial zu 0.01-0.02* [Castaldi says 0.01-0.026] *per Kilo für Kaninchen tödlich, die Allylisopropylbarbitursäure somit weit weniger giftig als jenes."* ("According to Castaldi Dial is fatal to rabbits in doses of 0.01 to 0.02 [Castaldi says 0.01 to 0.026] per kilogram; therefore allylisopropylbarbituric acid is much less toxic.") The figures given by Castaldi relate to the toxicity of Dial injected *intravenously*—a fact evidently overlooked by Pohl, Redonnet and the Hoffmann-LaRoche firm. Wiki found the dose of "dial-natrium" containing about 90 per cent of the acid given intra-arterially which arrested respiration and which, according to Wiki, would certainly have caused death had not artificial respiration been employed to be 0.024 Gm. per kilogram; the corresponding dose of the compound of allylisopropylbarbituric acid and diethylamine, containing 75 per cent of the acid, was 0.02 Gm. per kilogram.

One of the papers by Redonnet (*Arch. internat. de pharmacodyn. et de Therapy.* **25**:25 [properly 241], 1920) makes no mention of allylisopropylbarbituric acid. In the other paper (ibid. **30**:321, 1925) Redonnet describes one experiment in which he administered, by stomach to one cat, 0.01 Gm. of the allylisopropylbarbituric acid and to another 0.01 Gm. of Dial per kilogram. The temperature of the first cat fell to 35.3 and the respiration to 30 per minute, whereas the temperature of the other cat (the cat receiving the Dial) fell to 33.8 and the respiration to 12; the absorption, narcotic action, elimination, etc., were similar in the two animals. (It should be noted that the results are just the opposite of those obtained by Pohl; see the preceding.) Redonnet states that these results led the firm of Hoffmann-LaRoche to replace the "Dial" of "Somnifen" by the new hypnotic, thus obtaining a drug of the same activity, but the toxicity of which is a "little diminished" (the author further states that the fatal dose of the new "Somnifen" which contained allylisopropyl compound instead of "Dial," was, for rats, subcutaneously, 1.6 cc. per kilogram, whereas that of the old Somnifen was 1.4 cc.).

The two experiments of Pohl and Redonnet (which, as pointed out above, contradict each other), do not show that there is any significant difference as regards the ratio between the narcotic and the toxic actions of allylisopropylbarbituric acid and diallylbarbituric acid (the two compounds selected by the firm for comparison).

The third author quoted by the firm as having shown such a difference is Wiki (*Arch. internat. de pharmacodyn. et de therap.* **27**:117, 1922). This author has clearly expressed his own views on this subject in the following words (p. 161): "It is impossible for us to draw, from our experiments, definite conclusions as to the superiority of the one over the other" and further, that the diallyl and the allylisopropyl compounds seem to be practically equivalent, both having comparable advantages and disadvantages.

Wiki also made a number of comparisons between the diallyl and the allylisopropyl compounds on the one hand, and barbital and phenobarbital on the other. Since phenobarbital is used to a considerable extent for purposes distinctly different from those for which the other compounds are used, the question of its relative efficiency and safety is of less interest in this connection. Wiki states (p. 160) that to produce simple sleep, four to five times as much of barbital is necessary as of the allylisopropyl compound; he also states

(p. 128) that to arrest respiration 0.15 Gm. per kilogram of the latter and 1.01 Gm. (or 6.7 times as much) of the former is necessary. Wiki also describes experiments in which the animals were kept alive by means of artificial respiration and the administration of the drugs continued until death resulted from circulatory failure; 0.75 Gm. of the allylisopropylbarbituric acid and 3.46 Gm. of barbital (or 4.6 times as much) was necessary. The author also states (p. 129) that to produce anesthesia about five times as much barbital as of the allylisopropyl compound is necessary. Thus, whether the criterion for physiologic action is the production of simple sleep or of anesthesia, and that for toxicity is stoppage of the respiration or of the heart, there is a close parallelism between the physiologic (corresponding to the therapeutic) action and the toxic action; that is, toxic action increases in the same ratio as does the physiologic action. The only significant deviation from this is to be found in comparisons of the simple hypnotic doses with those causing arrest of the respiration (the cause of death unless artificial respiration is maintained): from these it would seem that, whereas only four to five times as much barbital as of the allylisopropyl compound is necessary to cause sleep, about 6.7 times as much is necessary to cause death. Thus, from the standpoint of use as a simple hypnotic (in which physicians are chiefly interested) the advantage lies with barbital.

The only point in which Wiki claims that the isopropyl compound is superior to barbital is in experiments on rabbits in which doses sufficient to cause anesthesia were given; in these he found the blood pressure slightly higher in the case of the animals anesthetized by the allylisopropyl compound than in those anesthetized with barbital (96 per cent, as compared with 84 per cent of the original pressure). Also after doses sufficient to paralyze the respiration (the animals being kept alive by artificial respiration), the blood pressure was somewhat higher in the case of the animals poisoned with the allylisopropyl compound (77 per cent of the original as compared with 55 per cent in the case of the animals poisoned with barbital). In similar experiments on a dog, however, barbital depressed the blood pressure less than did the allylisopropyl compound.

Lepper (*Arch. f. d. ges. Physiol.* **204**:498, 1924) states that dilute solutions of barbital constrict blood vessels, and Redonnet (*Arch. internat. pharmacodyn. et de therap.* **30**:327, 1925), states that barbital in therapeutic doses (in which physicians are most interested) causes a slight elevation of blood pressure; Redonnet quotes Castaldi as stating that the diallyl compound causes only a fall of blood pressure.

Thus, of the four papers cited by the firm in support of their claim that allylisopropylbarbituric acid "possesses the same hypnotic action as, for instance, diallyl-barbituric acid but is distinctly less toxic" the allylisopropyl compound is not mentioned in one; the conclusion drawn in another (the paper by Pohl) is based on an incomplete and misleading quotation (by Pohl) from another author (Castaldi) and shows nothing; a third paper quotes a single inconclusive experiment (which is also in conflict with the experiment of Pohl), and the fourth paper (by Wiki), instead of supporting the firm's contention, contradicts it in essential respects. The work of Fredet and Fabre on "tissue affinity, method and duration of elimination, etc.," has no bearing on the point under discussion, viz., whether in relation to its narcotic power the new compound is less toxic than other members of the barbituric acid series.

Frequent reference is made in trade circulars and the clinical reports, distributed by the Hoffmann-LaRoche Chemical Works, to Allonal as a "Hypno-Analgesic"; the hypnotic feature is especially emphasized at one time, the analgesic at another. The hypnotic action seems to be attributed chiefly to the presence of the "new hypnotic, allyl-isopropyl-barbituric acid," which "is not to be confused with other members of the barbituric acid series which have long been used as hypnotics" (although, as pointed out in the preceding, no evidence has been submitted to show that this compound has advantages over the similar compounds "which have long been used as hypnotics"). Since nothing is said as to analgesic properties of the "new hypnotic," those of "Allonal" are presumably due to the presence of amidopyrine, a drug which has been in use as an analgesic for nearly thirty years. In other words, the effort is made to combine in one preparation the hypnotic properties of barbital and the analgesic properties of amidopyrine. A circular letter begins:

> "Dear Doctor: The value of Allonal for quieting pain has been so thoroughly demonstrated and widely written about that many members of the profession have come to think of it only as an analgesic. Have you tried Allonal for its hypnotic effect? As an hypnotic the action of Allonal is splendid."

A later circular letter begins:

> "Suppose you had a patient suffering greatly and unable to sleep because of pain, and Morphine had failed to bring relief . . . would you not be glad to learn of a new nonnarcotic drug that had been tried by many members of the profession and found to be highly effective in such cases?"

And then again:

> "Queer, isn't it, how many people lie awake for hours at night fighting to go to sleep? Physically tired but mentally alert—too alert for sleep. . . . In these cases a reassuring talk on the part of the physician and just one Allonal tablet upon retiring usually gives very satisfying results."

And so on. Long lists are given of conditions in which Allonal has been successful, such as: "Multiple Neuritis," "Rheumatoid Arthritis," "Tabetic Pains," "Agitated Depression," "Paralysis Agitans," "Drug Addiction," "Alcoholic Poisoning," "Arteriosclerosis," "Paresis," "Trifacial Neuralgia," "Polyarthritis," "Tic-douloureux," "Postoperative Pain," "Inflammatory Glaucoma," "Cellulitis," "Nephritic Pain," "Paroxysmal Headache," "Carcinoma," "Chronic Asthma," "Chronic Pancreatitis," "Colitis," "Intercostal Neuralgia," "Neuralgia," "Mental Disorders," "Persistent Hiccough," "Gastric Crises in Tabes," "Mild and Severe Insomnia," "Menstrual Pains," "Neuritis," "Chronic Prostatitis," "Luetic Headache," "Insomnia without pain," "Painful Menstruation," "Trigeminal Neuralgia," "Bell's Palsy," "Hodgkin's Disease," "G. U. Conditions," "Dysmenorrhea," "Nervous Manifestations of Pregnancy and the Puerperium," "Dementia praecox," "Cerebrospinal lues," "Abscessed tooth," "Hemorrhoids," "Melancholia with drug addiction," "Carcinoma of the rectum," "Chronic asthma," "Mucous colitis with severe peristaltic contractions," "Headache," "Hemiplegic insomnia," "Post-operative Neuralgia," "Alcoholic Excesses," "Pelvic Pain in Women," etc., etc.

All of these and many other conditions are listed as having been relieved by this combination, in fixed proportions, of an hypnotic and an analgesic drug; the only individualization suggested is "1 to 2 tablets" for some and "2 to 4 tablets" for others. The Council believes that physicians should consider the needs of the individual patient to a greater extent than this: to give perhaps more of the hypnotic and less of the pain-relieving drug "in cases of insomnia without pain" and more of the analgesic in "carcinoma of the rectum," etc. In none of the clinical reports submitted by the firm does the author refer to observations in which either component of the drug was used separately or in which the relative proportion was varied; the absence of data on this subject deprives these reports of much of their value as arguments for the use of Allonal. The Council has long held that in the case of pharmaceutic preparations and mixtures "it is important that the prescriber should be *reminded constantly* of their potent ingredients."

Concerning the prescription of two drugs in the proper proportion, the firm states:

> "If the Council believes that the fixed proportions of Allyl-isopropyl-barbituric acid and Amidopyrine in Allonal are irrational . . . we are again sorry. We must state, however, that what seems in the Council's eyes irrational is only so when viewed from a purely idealistic standpoint; from a practical standpoint, unless the profession should be thoroughly enlightened by educational work on the part of some one properly qualified, unfixed proportions would certainly *prove a great deal more irrational.*"

The new hypnotic for which great superiority is claimed *has not been made available*; if the physician desires to use it *he is forced to give at the same time* amidopyrine, an antipyretic as well as analgesic drug which may not be needed and which of itself not infrequently causes untoward symptoms.

In this connection, the view of Redonnet (to whose writings the firm referred the Council for further information on the barbituric acid hypnotics) may be cited. Redonnet in his latest publication on this subject (*Arch. internat. de pharmacodyn. et de therap.* **30**:324, 1925) remarks: "Some have thought to augment the activity of these hypnotics [of the barbituric acid series] in associating them with various medicaments, especially with the analgesics and the alkaloids of opium." Among such mixtures of combinations are mentioned: "Veronacetin, Somnacetin, Veramon, Quiesan, Quieonal, Dialacetin, Allonal, etc."; after speaking of certain disadvantages of the mixtures of the barbituric acid hypnotics with the synthetic analgesics (such, for example, as disturbances of the heat regulating centers), he adds, "In cases of insomnia caused by pain better results may, however, be obtained with these preparations than with the hypnotics alone; but we believe that it is preferable to administer them separately in order to better graduate the respective doses of each medicament."

The Council finds Allonal unacceptable for New and Nonofficial Remedies because (1) the therapeutic claims advanced are deemed unwarranted by the facts; (2) the name is not descriptive of its composition, and (3) there is no satisfactory evidence that the administration of a mixture of allylisopropylbarbituric acid and amidopyrine in fixed proportion (or of a feeble chemical compound of these two that behaves in the stomach like a mixture) is rational.

The Council is prepared to consider the acceptance of allylisopropylbarbituric acid when it is offered in pure form and with claims that are supported by adequate evidence.

Correspondence

UNWARRANTED USE OF PHOTOGRAPH BY ANGIER CHEMICAL COMPANY

To the Editor:—A few days ago I received in my mail an advertisement of an emulsion of cod liver oil, made by the Angier Chemical Company, Boston. My photograph is on the cover of the advertisement and my name under it. No explanation is given. The inference may be that I am connected with the exploitation of this emulsion. The truth is that this is the first time I ever heard of it; I do not know where the photograph was secured and never gave permission for its use. It is, to say the least, an unwarrantable invasion of privacy, but it also lays me open to suspicion of being interested in the sale of a proprietary remedy. The advertisement has been widely circulated and apparently sent simultaneously to all parts of the country, so that any protest which might be made would come too late. I wish nevertheless to register a protest against this form of publicity, and I hope that physicians in general will frown on it until commercial companies learn that such methods do them more harm than good.

Alice Hamilton, M.D., Boston.

NEWSPAPER PUBLICITY REGARDING "ADJUSTMENT CURES" AT CORNELL UNIVERSITY

To the Editor:—It has come to my notice that there has been widespread newspaper publicity in regard to certain alleged discoveries at Cornell University of a cure for rheumatism, sciatica and numerous other diseases, and the reaction of the osteopaths, chiropractors and others to these newspaper articles makes it seem wise that there should be a statement of the facts.

An alumnus of the university and another physician of New York State, at their own request, were permitted to work in the anatomic laboratory of the Ithaca Division of the Cornell University Medical College. They desired to determine whether there was any anatomic basis that would explain a large number of symptoms which they claimed were relieved by certain manipulations which they performed. It was their opinion that these varied symptoms were caused by "sacroiliac dislocations" and that their manipulations "reduced" these.

No member of the staff of the medical college was engaged in the investigation, and the physicians conducting the inquiry were unable to demonstrate any anatomic basis that would explain either the symptoms or the results that they claimed to obtain. I do not know the source of the newspaper story.

Abram T. Kerr, Ithaca, N. Y.
Professor of Anatomy, Cornell
University Medical College.

"OXYGEN TREATMENT OF MALIGNANT EDEMA"

To the Editor:—In The Journal, May 1, appeared a clinical note on the "Oxygen Treatment of Malignant Edema," by Dr. R. P. Roantree, Elko, Nev. The author stated that he did not find in the literature any mention of a patient treated in this manner.

It is only fair to give the credit of the method to Professor Thiriar of Brussels, who described it as far back as 1899. Since that time the oxygen treatment has been extensively used in various pyogenic conditions, but has met with special favor in the treatment of the anaerobic infections. During the World War we found it efficient when gas gangrene was a prevalent complication. During the last years of the war it was not used frequently because prophylaxis was successful and because better curative methods had been found.

The literature on the subject is quite extensive; may I refer to these few papers:

Thiriar, Jules: De l'emploi de l'oxygène en chirurgie, *Bull. Acad. roy. de méd. de belgique,* 1899.

Wohlgemuth, Heinz: Der Wert des Sauerstoffs in der Chirurgie, in Handbuch der Sauerstofftherapie, Berlin, 1906.

Phipps, E. F.: De l'emploi en thérapie chirurgicale de l'oxygène, Thèse de Paris, 1916.

Charles L. Janssen, M.D., New York.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DIAGNOSIS OF SCARLET FEVER

To the Editor:—We are having an epidemic of scarlet fever, and it is so mild that it is sometimes impossible to say whether it is scarlet fever or not. I had a sound boy of 12 in whom I diagnosed scarlet fever on the strength of a rash on his chest, a suggestive tongue and a slightly red throat. He was slightly ill, and his mother would hardly accept my diagnosis. A few days later she had the same symptoms. Then a younger brother got scarlet fever from head to foot, and they accepted the cases as scarlet fever. Then a bigger brother got slightly sick. The boy first taken ill returned to school, and two days ago fell and struck the back of his head on a rock. His wound pained him when I saw him; he vomited, had headache and had fever to 104. I attributed this to the wound, which had scabbed over, and which on being opened yielded pus. Now comes the part that puzzles me: Today he has a typical scarlet rash all over, a suggestive tongue and a red throat. Is it possible to have scarlet fever twice so close together?

A. C. Muller, M.D., Durham, Calif.

Answer.—It is impossible from the information given to clear up all the points raised. The possibility of concurrent epidemics of scarlet fever and German measles must be considered. The presence of a moderate polymorphonuclear leukocytosis and hemolyzing streptococci in the throat would speak in favor of scarlet fever. In scarlet fever a positive Dick test before or at the beginning of the sickness, with a negative one after recovery, is usual, while this would not be true in German measles. Two attacks of scarlet fever in a person may occur, and there is no arbitrary time that must elapse between them. A second attack, usually spoken of as a recurrence, may occur after about a month.

HAIR DYES

To the Editor:—In The Journal, Nov. 14, 1925, p. 1578, two prescriptions were given for dyeing the hair. It is true that they dye, but the hair does not get quite dry and it stains afterward. Is there any special technic for use?

F. Oduber, M.D., Pto. Cumarebo, Venezuela.

Answer.—The moisture is probably due to the glycerin in the first solution. This should be easily removed by washing the hair with water after the use of the second solution. If desired, the first solution may be made up with half the amount of glycerin, which may lessen the difficulty.

SCARLET FEVER AND GERMAN MEASLES

To the Editor:—Scarlet fever cases were reported in three directions from this village, while from the fourth direction came reports of German measles (rubella). My first case occurred early in February and was a mild but typical case of scarlet fever. Fifteen days later a younger brother developed a mild and brief illness which corresponded very nearly to rubella as usually described. April 28, the first child was again showing the symptoms of scarlet fever. Is this second attack a flare up of a hidden infection or a reinfection? There are now about a dozen cases of scarlet fever in this vicinity. Is a papular form of eruption, especially a "goose-flesh" eruption, characteristic of many scarlet fever cases, sufficiently distinctive to be a differential point? Does "goose-flesh" attract attention in rubella?

Assume that both diseases are present in a locality and that the prevailing scarlet fever is mild and atypical. In one house are three children, 8, 6 and 1½ years of age. The oldest child has very mild scarlet fever. The older children were exposed at the same time to the same infection. The parents consent to giving the baby the contents of Lilly's "Prophylactic Package" of antitoxin. Should the 6 year old be given a similar prophylactic dose or the larger treatment dose?

A child of 9 years received three vaccination treatments in February. Ten days ago he developed mild scarlet fever. The mother of this child herself had one "vaccination" treatment (injection) as soon as the boy became ill. One week later she asked for her second shot. The vials containing the usual second and third doses were accidentally crushed; so about half of a prophylactic package syringe was given. That night her arm became very painful and a large red area about 3 by 4 cm. developed at the site of this injection. Presumably this is an irritating and considerably larger dose than the usual second injection. In consideration of this, will it be safe to give her a third dose in two weeks or less after the second injection? Please omit name and address.

M.D., South Dakota.

Answer.—It is not always possible to differentiate German measles from scarlet fever by the appearance of the rash or other symptoms. In scarlatinal rashes, the intradermal injection of from 0.1 to 0.2 cc. of scarlet fever antitoxin usually results in a local blanching. Scarlet fever antitoxin does not blanch the rash of German measles.

It is not possible to say from the symptoms described in the letter whether the first case was one of German measles or scarlet fever. It may be pointed out, however, that second attacks of scarlet fever, while uncommon, may occur.

The passive immunization from the administration of antitoxin cannot be expected to last more than two weeks. Prophylactic injection of antitoxin is an emergency measure to prevent the development of scarlet fever in susceptible persons already perhaps infected. Various manufacturers have placed on the market prophylactic doses of scarlet fever antitoxin that differ considerably in antitoxin content. In some instances the amount of antitoxin has been too small to afford protection. Firms licensed by the Scarlet Fever Committee are required to put out a prophylactic dose of scarlet fever antitoxin which is at least one-half the therapeutic dose.

Without information as to the dosage of toxin used in immunizing the 9 year old boy, it is not possible to say what result might be expected. The following dosage is recommended: First, 500 skin test doses. Second, 1,500 skin test doses. Third, 5,000 skin test doses. Fourth, 15,000 skin test doses. Fifth, from 25,000 to 30,000 skin test doses.

Following these five doses, given at intervals of one week, a skin test should be made, and if it is not entirely negative, the last dose is repeated until the skin test is negative.

It may be that the three doses did not contain enough toxin to immunize the child, and that the present illness is scarlet fever.

In the case of the mother who received one "vaccination" treatment and not the others because of the broken vials, there seems to have been a confusion between the toxin employed in graduated doses for the more permanent active immunization, and the prophylactic dose of antitoxin, which is usually distributed in syringes and used for temporary passive immunization. The mother probably received one dose of toxin, and then one half of a prophylactic dose of antitoxin. Neither would be sufficient to protect her from scarlet fever. No mention is made of a skin test on the mother. A negative skin test would indicate that she did not require immunization.

Connecticut March Examination

Dr. Robert L. Rowley, secretary of the Connecticut Medical Examining Board, reports the written examination held at Hartford, March 9-10, 1926. The examination covered 7 subjects and included 70 questions. An average of 75 per cent was required to pass. Of the 15 candidates examined, 12 passed and 3 failed. The following colleges were represented:

College	Year Grad.	Per Cent
PASSED		
Yale University School of Medicine	(1924)	83.8,
	(1925)	77.2, 81.2, 82.7, 86.3
Georgetown University School of Medicine	(1925)	83.3, 87

Missouri March Examination

Dr. James Stewart, secretary of the Missouri Board of Health, reports the written examination held at Jefferson City, March 9-11, 1926. The examination covered 15 subjects and included 128 questions. An average of 70 per cent was required to pass. Of the 22 candidates examined, 20 passed and 2 failed. The following colleges were represented:

College PASSED	Year Grad.	Number Passed

Book Notices

Intestinal Tuberculosis. Its Importance, Diagnosis and Treatment: A Study of the Secondary Ulcerative Type. By Lawrason Brown, M.D., Chairman of the Medical Board of the Trudeau Sanatorium, Saranac Lake, New York, and Homer L. Sampson, Roentgenographer of the Trudeau Sanatorium, Saranac Lake, New York. Cloth. Price, $4. Pp. 304, with 112 illustrations. Philadelphia: Lea & Febiger, 1926.

This is a thorough discussion of the subject; more than that, it carries a significant message, based on the authors' rich experience. Intestinal tuberculosis is not a terminal and hopeless complication of pulmonary tuberculosis, yielding to no therapeutic efforts, as generally represented in textbooks; if diagnosed early, it is as amenable to treatment as an incipient or moderately advanced pulmonary tuberculosis. An extensive statistical presentation of symptoms and signs renews forcibly the impression of the protean character of the disease and of the impossibility of a correct diagnosis. But the authors make the assertion, well substantiated by their statistics, that a correct observation of certain filling-defects after a radiopaque meal or enema and definite alterations in the motility of the intestines make it possible to diagnose ulcerations correctly in approximately 100 per cent. In the chapter on pathologic anatomy (which is all too brief) it is pointed out that Gardner found much tendency to spontaneous healing, rendered futile, as a rule, by the simultaneous spread of the disease. But in patients who had been treated a considerable length of time, complete healing had occurred with epithelial regeneration. The treatment consists of heliotherapy or, in Saranac Lake preferably, irradiation with the mercury vapor quartz lamp. Since heavy dosage of rays is given over the entire surface of the body, it is surprising that no mention is made of the effect on the pulmonary process. The experience has been made frequently, here and in Europe, that certain pulmonary processes react so severely to ray treatment as to make thorough heliotherapy of a concomitant extrapulmonary focus impossible. Of a group of seventy-four patients treated with the lamp, 31 per cent were cured (no roentgenologic signs of the disease could be detected any more) and 65 per cent were considerably benefited. These figures alone show that every one who treats tuberculous patients should study seriously the authors' methods of diagnosis and treatment.

Lehrbuch der speziellen Pathologie und Therapie der inneren Krankheiten. Fur Studierende und Aerzte. Von Professor Dr. Med. Adolf Strümpell, Direktor der medizinischen Klinik der Universität Leipzig. Von Professor Dr. Med. et Phil. Carly Seyfarth, Assistent an der medizinischen Klinik der Universitat Leipzig. Twenty-fifth edition. Paper. First Volume. Pp. 872, with 147 illustrations. Second Volume. Pp. 985, with 200 illustrations. Leipsic: F. C. W. Vogel, 1926.

Shortly before his death, Strümpell wrote in his autobiography: "December 24, 1881, in the afternoon, I sat down at my writing-table and proudly traced these words in large letters on the uppermost sheet of a thick mass of paper, 'First Chapter. Typhoid Fever.' That the book thus begun should have such unusual success and that I forty-two years later, in my seventy-first year, should be working on the twenty-fifth edition, I then could neither foresee nor assume." Of this book, 95,000 copies in German have been sold, and it has appeared in English, French, Russian, Spanish, Italian, Greek, Turkish and Japanese translations, in some cases in several editions. A translation by Herman F. Vickery and Philip Comps Knapp of Boston from the second and third German editions was published by Appleton & Co. in 1892, and the fourth edition, based on the seventeenth German, appeared in 1911. Strümpell's textbook is undoubtedly the most widely used book in its field of modern times. While translated into more languages than any other similar book, Osler's Practice appears to have exceeded it in the numbers sold of the original editions. In a presentation copy of his sixth edition in 1905 Osler writes, "This is number 62 of the first 105,000 copies printed." Professor Seyfarth began to collaborate with Strümpell in the revision for the twenty-second edition. Strümpell himself worked on the present edition since 1923, giving particular attention to his favorite section, nervous diseases, and that section now appears as he left it. The other parts of the book have been revised by Seyfarth. Thorough and dependable, clear and concise, Strümpell's book is noted especially for its masterly presentation of nervous diseases. Students and practitioners alike from the first have found it a reliable guide in the study of internal diseases, and the twenty-fifth revision fully merits the same confidence and use as its predecessors.

Chemical Pathology. Being a Discussion of General Pathology from the Standpoint of the Chemical Processes Involved. By H. Gideon Wells, Ph.D., M.D., Professor of Pathology in the University of Chicago and in Rush Medical College, Chicago. Fifth edition. Cloth. Price, $8.50. Pp. 790. Philadelphia: W. B. Saunders Company, 1925.

Eighteen years ago, the first edition of this book was written. The present edition appears five years after its immediate predecessor. From its first edition the aim of the work has been to gather from the fields of pathology, chemistry, physics, general medicine and allied sciences such material as would contribute to a consideration of pathology from the chemical point of view. The result has been recognized among authorities as unique, scholarly, logical and usable. Its place cannot be taken by any other book, either as a source of references to relevant periodical material or as a valuable body of subject matter in itself. In the preface to the present edition, the author points out that the preparation of a briefer or of an exhaustive work would have been comparatively easy. To select, however, that which is valuable and stimulating, even though it may not have become completely established, is obviously a more difficult task. In order to adhere to a policy of compression without undue exclusion, the book has been almost entirely rewritten and new material included. At the same time, preliminary discussion of principles now generally known has been omitted. The book continues, admirably, to fill its place among standard, authoritative works.

Allen's Commercial Organic Analysis. A treatise on the properties, modes of assaying, and proximate analytical examination of the various organic chemicals and products employed in the arts, manufactures, medicine, etc., with concise methods for the detection and estimation of their impurities, adulterations, and products of decomposition. Volume IV, special characters of essential oils; resins, india-rubber, gutta percha, balata, and allied substances; the constituents of essential oils, and allied substances; the general characters and analysis of essential oils. Edited by Samuel S. Sadtler, S.B., Member American Institute of Chemical Engineers, Elbert C. Lathrop, A.B., Ph.D., Member American Institute of Chemical Engineers, and C. Ainsworth Mitchell, M.A., F.I.C., Editor of "The Analyst." Fifth edition. Cloth. Price, $7.50. Pp. 648. Philadelphia: P. Blakiston's Son & Co., 1925.

The new volume of this work is divided into five chapters: one a short treatise on resins; the second on india rubber, gutta percha, balata and allied substances; the other three on the essential oils. In the last three chapters are considered (1) various individual oils, with brief statements concerning the source, chemical content, physical properties, impurities and possible adulterants; (2) some of the constituents from a distinctly chemical point of view, and (3) the analytic methods applicable to the essential oils, written in epitomized form. The reediting has been quite complete: in fact, the volume has been almost entirely rewritten, some of the old work having been deleted and new work inserted. Much of the information is of little value to those not actively engaged in the manufacture or analysis of cosmetics, essential oil preparations or pharmaceutic products, and the book, therefore, will be of chief interest only to those engaged in such manufacture or analysis. For these the volume is a valuable reference work because (1) it contains a vast amount of carefully compiled material, and (2) the abundance of references to the original literature supplements the sometimes abbreviated discussions.

Your Hair and Your Health. By Oscar L. Levin, M.D., Chief of Clinic, Cornell University Medical College and Clinic. Cloth. Price, $1.50. Pp. 163, with 10 illustrations. New York: Greenberg, 1926.

This is a popular book on the hair and things that pertain thereto. It is written in sprightly style and holds well the reader's attention. As a matter of fact, the style is perhaps too sprightly. It leads the writer into a way of making positive statements that are at best opinions—certainly not facts. The thesis of the book is that "healthy hair needs a healthy constitution" (p. 13). That is a hard thesis to maintain in the face of the battalions of bald-headed men who are certainly as healthy as the rest of us and, we are inclined to believe, a little tougher. "Hairs do grow thicker and stiffer from shaving, however, and so does the hair of women who have undergone bobbing. When so-called [why so-called?] superfluous hair is temporarily removed by shaving, pulling or mechanical depilatories, the succeeding hairs are also thicker and stiffer" (p. 14). That is all opinion which is in conflict with some very careful studies. Who is in position to say now that the hair of women grows thicker from bobbing? It has not had any appreciable effect in that direction on the men who have been bobbing their hair for geological ages compared with the time women have been doing it. "At the bottom of many cases of temporary or permanent baldness . . . are emotional disturbances, such as worry, fright, shock and nervous exhaustion. . . . Dissipation, indirectly, can cause baldness and there may be a grain of keen observation in the tradition about the bald-headed front row of tired business men" (p. 23). Who knows the facts on which such positive statements are made? And what of this pathology? "Emotional disturbances affect the nerves. When the nerves are injured or diseased, the blood supply is deranged. The hair suffers. . . . When these disturbances are long continued, the blood supply is disturbed more permanently and the hair suffers with the rest of the system" (p. 23). The difficulty is that in his general statements about the pathology of baldness, the author apparently makes no distinction between the baldness symptomatic of various diseases and following acute diseases and common baldness—premature senile baldness; so that he makes statements that the lay reader thinks refer to the kind of baldness he knows and is interested in, while as a matter of fact the author's statements, if they apply at all, apply only to special and unusual kinds of baldness and cannot be justified as statements about common baldness at all. If one turns a little farther and gets away from the pathology of baldness, one finds statements like this: "When water is mixed with soap it sets free the alkali, which attacks and saponifies the grease upon which it is rubbed; hence the strength of a soap is determined by the amount of its alkaline contents" (p. 48). The explanation of the action of soaps is nothing of the sort. Water does not decompose soap and set free the alkali. Probably the sole thing that makes soap detergent is the fact that a solution of soap in water is an emulsifying agent; it emulsifies grease and dirt and in that way rids the skin of them. The same thing can be done to a limited extent with an emulsion of tragacanth. If it were free alkali that made soaps useful, the simpler plan would be to wash in a solution of potassium hydroxide and be done with it. These are almost random quotations. Probably two or three times as many inaccurate statements could be picked out in the same pages. Such inaccuracies are of more than academic interest. Lay readers will accept the book as authoritative and follow its teachings—and be none the better for it. The public wants—and perhaps needs—correct information on the subject; but it has already an oversupply of misinformation. This work cannot be called a serious effort to cover the subject or one that represents the actual state of our knowledge—or our ignorance.

Thérapeutique chirurgicale. Par P. Lecène, Professeur à la Faculté de médecine de Paris, et R. Leriche, Professeur à la Faculté de médecine de Strasbourg. Tome III. Abdomen et organes génito-urinaires. Par P. Lecène. Cloth. Price, 50 francs. Pp. 645. Paris: Masson & Cie, 1926.

The author takes up in detail the pathologic types of malformation, injury or disease in each region and organ of the abdomen. He describes briefly the characteristic anatomic, pathologic and clinical features, and then discusses in great detail the indications and contraindications for surgical treatment and the methods available, with their reported final results. Recommendations for surgical treatment are based largely on the experience of the author, but he reviews some of the literature on each subject and gives the references. He considers the surgical affections of the abdominal wall, the peritoneum, the stomach, the duodenum, the intestines, the liver, the bile ducts, the pancreas, the spleen, and the genito-urinary tract of the male and the female. The details of surgical technic are not considered, but the surgical methods are discussed. The absence of illustrations is not a serious defect, since the volume is not meant to replace, but to supplement, works on operative surgery, pathology and anatomy. The book is valuable because it reflects the experience and judgment of the author, giving, along with his opinions, the present generally accepted treatment of abdominal disorders.

A Text-Book of Pharmaceutical Chemistry. By Arthur Owen Bentley, Ph.C., Director of the Department of Pharmacy, University College, Nottingham, and John Edmund Driver, M.Sc., A.I.C., Lecturer in Chemistry, University College, Nottingham. Cloth. Price, $6. Pp. 456. New York: Oxford University Press, 1925.

This book is primarily written for those studying for the Pharmaceutical Society's diploma and degrees in pharmacy, and contains the pharmaceutic and organic chemistry—both theoretical and practical—necessary for the chemist and druggist qualifying examination. The book is divided into two parts, inorganic and organic. The former includes a description of the nonmetallic substances of the British Pharmacopeia, with tests for impurities and detailed methods of analysis described in the British Pharmacopeia. Part II comprises the organic, describing methods of detection, ultimate analysis of the elements and a concise general survey of the subject, including a description of the organic substances of the British Pharmacopeia. The appendix contains useful schemes for the identification of the more common inorganic and organic compounds. Provided the text is used as the authors intend, that is, only by those who have completed a course in systematic chemistry, it may serve a useful purpose, although it is of little value to those studying pharmacy in the United States, as it does not include the U. S. Pharmacopeia X.

EVOLUTION, GENETICS AND EUGENICS. By Horatio Hackett Newman, Professor of Zoology in the University of Chicago. Cloth. Price, $3.50. Pp. 639, with 99 illustrations. Chicago: University of Chicago Press, 1925.

The first edition of this book appeared in 1921. So great was its success that it passed through six printings and demanded a second edition, which is represented by the present volume. It is actually an encyclopedia on the present status of our knowledge of evolution culled from many sources. It includes even a brief chapter on the Scopes trial and the present questioning of our knowledge and beliefs in this field. For the student of biology or the general reader it is perhaps the most valuable volume on the subject. A glossary and a good bibliography supplement the text.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

THE CLINICAL INTERPRETATION OF THE WASSERMANN REACTION. By Dr. Robert A. Kilduffe, A.B., A.M., M.D., Director Laboratories, Atlantic City Hospital. Cloth. Price, $2.50. Pp. 203, with charts. Philadelphia: Lea & Febiger, 1926.

Monograph with survey of literature and details of technic.

CONTRIBUTIONS TO OPHTHALMIC SCIENCE. Dedicated to Dr. Edward Jackson in Honor of his Seventieth Birthday, March 30, 1926. By his Pupils and Colleagues in the United States. Cloth. Pp. 319, with illustrations. Menasha, Wisconsin: George Banta Publishing Company, 1926.

Festschrift for an American pioneer in opthalmology.

SIR WILLIAM OSLER. Memorial Number. Appreciations and Reminiscences. Bulletin No. IX of the International Association of Medical Museums and Journal of Technical Methods. Cloth. Privately issued. Pp. 632, with illustrations. Montreal, 1926.

Collection of many personal and historical Osleriana.

DISEASES OF THE SKIN. By Richard L. Sutton, M.D., LL.D., F.R.S., Professor of Diseases of the Skin, University of Kansas School of Medicine. Sixth edition. Cloth. Price, $12. Pp. 1303, with 1158 illustrations. St. Louis: The C. V. Mosby Company, 1926.

Up-to-date edition of well established textbook.

DIATHERMY: With Special Reference to Pneumonia. By Dr. Harry E. Stewart, Director, New Haven School of Physiotherapy. Second edition. Cloth. Price, $3. Pp. 228, with 45 illustrations. New York: Paul B. Hoeber, Inc., 1926.

Enthusiastic monograph on this method.

PLANNING A TUBERCULOSIS SANATORIUM. By T. B. Kidner. Technical Series No. 6. Paper. Pp. 36, with illustrations. New York: National Tuberculosis Association, 1926.

Authoritative practical pamphlet prepared under auspices of national association.

THE TECHNIC OF ORAL RADIOGRAPHY. By Clarence O. Simpson, M.D., D.D.S., F.A.C.D. Cloth. Price, $5. Pp. 207, with 165 illustrations. St. Louis: The C. V. Mosby Company, 1926.

All the details for securing good roentgenograms of the teeth.

BERNHARD HEINE'S VERSUCHE ÜBER KNOCHENREGENERATION. Sein Leben und seine Zeit. Von der deutschen Gesellschaft für Chirurgie, anlässlich ihrer 50. Tagung den Fachgenossen unterbreitet. Herausgegeben von der anatomischen Anstalt 'der Universitat Wurzburg. Mit einem Vorwort von Professor Dr. A. Bier. Paper. Price, 7,50 marks. Pp. 224, with 106 illustrations. Berlin: Julius Springer, 1926.

DIE CHIRURGIE: Eine zusammenfassende Darstellung der allegemeinen und der speziellen Chirurgie. Herausgegeben von Prof. Dr. M. Kirschner und Prof. Dr. O. Nordmann. Lieferung 8. IV. Band. Die Chirurgie des Ohres. Von Prof. Dr. A. Blohmke. Paper. Price, 16 marks. Pp. 359-636, with 182 illustrations. Berlin: Urban & Schwarzenberg, 1926.

OVER AETIOLOGIE, DIAGNOSTIEK EN THERAPIE VAN CHRONISCH RHEUMATISCHE AANDOENINGEN. Door J. van Breemen, Geneesheer-Directeur van het Instituut voor physische Therapie te Amsterdam. Paper. Pp. 246. Rotterdam: W. L. & J. Brusse, 1926.

Treatment of Fracture—Failure to Use Roentgen Rays

(Wright v. Conway (Wyo.), 241 Pac. R. 369)

The Supreme Court of Wyoming, in affirming a judgment on a verdict directed for the defendant physician, says that he was employed to treat a fracture of the femur of the plaintiff's right leg, the fracture being a simple and transverse one at or a little above the junction of the lower and middle third of the femur. The method of treatment adopted was that of Buck's extension. The court finds negligence on the part of a physician sometimes defined, generally, as consisting in his doing something that he should not have done, or in omitting to do something that he should have done. The negligence must appear from expert testimony, and that it caused the condition complained of, unless relating to a matter of common knowledge. Neither failure to possess or use ordinary skill, nor that the result complained of was brought about thereby, should be supported merely by theory, conjecture or inference, but should be based on tangible, substantial evidence which the court and jury may grasp and understand.

That the defendant ascertained and diagnosed correctly the nature of the injury was beyond controversy; all the evidence showed it. There was an attempt to show that the extension may have been improperly applied on the theory that the defendant erred as to the location of the fracture; but the evidence fell far short of that, and the court cannot well understand how he could have correctly ascertained the nature without at the same time discovering the location of the fracture. Having correctly ascertained the location and nature of the fracture, a roentgenogram for that purpose was unnecessary. Failure to secure a union during the period of the defendant's treatment (which was less than five weeks), or even longer, had it been continued, would not, alone, establish negligence, or even be a ground for an inference thereof, since a successful result is not guaranteed, and the general rule is that an unsuccessful result does not, alone, establish negligence or justify an inference thereof.

Unless negligence consisted in the failure to use the roentgen ray within a few days after the initial treatment and occasionally thereafter during the first four weeks, and especially on the appearance of a knot underneath the leg, which, according to one physician's testimony, may have indicated malapposition of the bones, there was no evidence of negligence in the defendant's diagnosis and treatment. But it was not alleged, nor did it appear in the evidence, that a roentgen-ray machine was available at any time prior to the use of one when the leg was found to be swollen, about four weeks after the application of the extension. The expert witness apparently assumed that one was available at all times mentioned in his testimony, or else intended to say that it should be used whether available or not. But the law does not exact the impossible of the medical practitioner. In the court's investigation it found no case wherein the failure to use the roentgen ray was held to be negligence, where it did not directly appear that such an instrument was available, or there was no suggestion to the contrary. Negligence being charged in the defendant's failure to bring to his aid this comparatively new apparatus, which the court does not understand is yet recognized as a necessary or usual part of the equipment of a general medical practitioner's office, at least in the ordinary community, the court thinks it was the plaintiff's duty, under the rule of the burden of proof in malpractice cases, to show by his evidence that such a machine or apparatus was available for the defendant's use, or might at least have been easily procured. That ought not to have been difficult if such an instrument was available. Certainly, if one was at the hospital, that might easily have been shown, or if in the office of any other practitioner in the city. Moreover, failure to use roentgen rays, even though available, was not necessarily negligence.

Negligence was alleged in burning the flesh by the careless application of hot irons or bottles; but it did not appear that the defendant did anything more than to suggest or prescribe the hot applications. It was not shown that he applied them, or that he was present when they were applied. If applied by a nurse at the hospital, there was nothing to show that her relation to the defendant was such as to make him responsible for that action. She might have been employed by the plaintiff. Without further showing than that found in this case, the defendant would not be liable for the burns or blisters resulting from such hot applications.

Testes Are "Members"—on Presumption of Sanity

(People v Saylor et al (Ill), 149 N. E. R. 767)

The Supreme Court of Illinois holds that castration is within the terms of the Illinois statute which is directed against the removal or disabling of any limb or member of any person with the malicious intent to maim or disfigure him There can be no question that the testes are members of a man, and that their removal maims and disfigures him. Mayhem by castration seems always to have been a felony at common law.

An instruction which began by telling the jury that every person accused of crime is presumed to be sane until the contrary is shown was erroneous The law does not presume every person accused of crime to be sane until the contrary is shown. The only effect of the presumption of sanity is to require the introduction of evidence tending to prove insanity. When that is done, the presumption no longer prevails. It does not continue until the contrary is shown. The question of sanity or insanity is then to be determined from the whole evidence, without any reference to the presumption. The rule, as stated in the instruction, in effect imposed the burden of proof on the defendant It is not essential that insanity should be shown. All that is required of the defendant is evidence sufficient to raise a reasonable doubt of sanity The presumption of sanity cannot be considered by the jury in determining whether the defendant is sane or insane. Whenever evidence is introduced tending to show that the accused was insane at the time of committing the act charged as a crime, the burden devolves on the state to prove beyond a reasonable doubt, regardless of the presumption, that at the time of the commission of the act the accused was sane.

Validity of Law Relative to Drugless Healers

(People v Lewis (Mich), 206 N. W R. 553)

The Supreme Court of Michigan, in affirming a judgment of conviction of the defendant of the crime of practicing medicine without a certificate of registration or license, says that he was a graduate of a school of chiropractic and contended that the medical practice act, requiring registration and fixing qualifications of all persons practicing medicine is unconstitutional, unreasonable, arbitrary, and violates the fourteenth amendment to the federal constitution It was insisted that the statute operates to prohibit chiropractors from obtaining a license, because it requires them to pass an examination before a medical board in subjects which no school of chiropractic teaches, and which are not used by them in the practice of their profession The court takes it that the defendant desires to practice a system of treatment of human ailments or diseases without the use of drugs If so, is it unreasonable to require him to pass an examination before a board of qualified experts in the subjects of anatomy, histology, embryology, physiology, chemistry, bacteriology, pathology, diagnosis, hygiene and public health?

It is within legislative power to require persons practicing treatment of human ailments or diseases without the use of drugs to possess knowledge of organic structure, intimate structure of tissues, embryonic evolution, functions of the body, molecular and atomic structure of bodies, microorganisms, science of diseases, morbid processes observable in various diseases of organs, recognition of disease by its symptoms, science of health, and efforts made and measures and precautions deemed advisable for the promotion and protection of public health This power has been exercised, and the regulation provided must stand, unless violative of rights guaranteed by the state or the federal constitution. The court finds no limitation on the subject in the state constitution, and it can conceive of no deprivation of the equal protection of the law in requiring drugless healers to understand the subjects mentioned. The fact that the defendant had not received instruction in some of these subjects offered no objection to the validity of the law. This court declines to indict the medical profession of design to annihilate the system of chiropractic adjustment and the legislature of supinely surrendering the lawmaking power in aid thereof. It may be that no chiropractic school teaches all the subjects mentioned, and chiropractors feel that a knowledge thereof is unnecessary and unused in their school of practice, but this affords no reason for requiring the legislature, in recognition thereof, to enact no law not in conformity therewith.

While the court thinks that all questions presented fall within the opinions of this court in *Locke* v. *Circuit Judge*, 184 Mich 535, 151 N. W. 623, and *People* v. *Rose*, 218 Mich. 642, 188 N. W. 417, it has examined the points anew, and finds the great weight of authority against every contention advanced. The cases cited by the defendant were clearly distinguishable from, or so contrary to, the former decisions of this court and the overwhelming weight of authority as to render review thereof unnecessary.

No school may fix a standard of education, and thereby entitle its graduates to practice any branch of the healing arts, regardless of legislation, and no graduate can of right demand that legislation accord with what he has been taught The law recognizes chiropractic adjustments or treatments, and fixes the standard of knowledge deemed essential to a proper practice thereof The legislature took a comprehensive view of the public welfare in regulating the practice of medicine What this court has said is not in disparagement of drugless healing The court decides only the legal questions presented, and leaves the policy of the law, within legitimate limits, to the legislative power.

Testimony Not Deemed Expert—Characteristics of Age

(In re Cooper's Estate (Iowa), 206 N. W. R. 95)

The Supreme Court of Iowa, in holding that a motion to direct a verdict for the proponents of the will contested in this case was rightfully sustained, says that a physician testified that at one time he was called to attend the testator for some physical ailment Aside from that he never made any examination of him, nor any observation to determine his mental condition He saw him and observed him as he saw and observed other people, on the street or in his business, but he did not claim that he gave any special attention to the testator as to his mental condition He described largely his physical condition He was also asked whether in his opinion the testator was of sound or unsound mind The testimony of this physician was offered in the case, and it appeared that he would have answered, if permitted, that the testator, during his later years, became childish and appeared to be senile, that the witness thought there was mental decay. As to the condition of the testator's mind, the physician said, "I wouldn't consider it sound." Under this record, the supreme court does not feel that the testimony of the physician rose to the dignity of expert testimony.

There was no showing that the testator was afflicted with the diseases incident to advancing years, excepting that the physician said that he saw evidences of senility. There was no contention that the testator's talk was irrational or that his thoughts were disconnected. He was probably peevish, childish, and made himself obnoxious by continually repeating the stories of his early life. But all these matters go with advancing years, and are not unexpected when it is considered that this man was 76 years of age when he made the first will, and 82 when the codicil was made. There was nothing in the record to show that he was so lacking in mental capacity as to be unable intelligently to remember and identify the property he possessed and the natural objects of his bounty, and intelligently to dispose of it. This is the ultimate measure of the mental capacity that the law requires of a testator Will contests must turn largely on the facts incident to each case, and it is difficult to lay down a rule in such matters.

Society Proceedings

COMING MEETINGS

American Ophthalmological Society, Hot Springs, Va., June 14-16. Dr. Emory Hill, Professional Building, Richmond, Va., Secretary.
Associated Anesthetists of the United States and Canada, Nottingham, England, July 20-23. Dr. F. H. McMechan, Avon Lake, Ohio, Sec'y.
Montana, Medical Association of, Billings, July 16-17. Dr. E. G. Balsam, 222 Hart-Albin Building, Billings, Secretary.
New Jersey, Medical Society of, Atlantic City, June 17-19. Dr. J. B. Morrison, 97 Halsey Street, Newark, Secretary.
North Carolina, Medical Society of the State of, Wrightsville Beach, June 15-17. Dr. L. B. McBrayer, Southern Pines, Secretary.
Oklahoma State Medical Association, Oklahoma City, June 22-24. Dr. C. A. Thompson, 609 Barnes Building, Muskogee, Secretary.
Wyoming State Medical Society, Lander, July 12-13. Dr. Earl Whedon, Sheridan, Secretary.

ASSOCIATION OF AMERICAN PHYSICIANS

Forty-First Annual Meeting, held at Atlantic City, N. J., May 4-5, 1926

(Continued from page 1794)

Experimental Production of Meningocerebral Tolerance in Acute and Subacute Lead Poisoning

Dr. C. V. Weller, Washington, D. C.: There is a general feeling that there is no such thing as an acquired immunity to lead poisoning, but there is evidence among the older writers that those exposed to lead, who develop convulsions early, do not develop poisoning later, when given the same exposure, although there may be exacerbations of poisoning with other minerals. In uranium nephritis, the body seems also to gain a certain tolerance to heavy mineral poisoning. We have chosen the guinea-pig as an experimental animal, as it shows clearly the convulsive manifestations indicating cerebral injury. The dosage is given by mouth in capsules, and the size of the dose makes no difference if it is given regularly. The nervous system reactions are shown by tonic and clonic contractions. Necropsy shows congestion and edema of the cortical cells. When the animals are given a rest from the poison and then exposed again later, we find that their resistance is increased to a marked degree to a much larger dosage. We have also noted this type of resistance in individuals who have been exposed to metallic poisoning.

DISCUSSION

Dr. W. E. Dixon, Oxford, England: Dr. Weller has shown conclusively that there is a tolerance to lead poisoning produced under these conditions. If the tolerance is of the nature that he assumes it to be, it is obviously of great importance; but is he sure that the tolerance is not due to the fact that the lead was not absorbed?

Dr. W. F. Hamilton, Montreal: Did Dr. Weller note any difference in the reactions in the different sexes, in connection with industrial lead poisoning cases?

Dr. C. V. Weller, Washington, D. C.: I have no evidence on the excreta or the tissues of killed animals. I think the lack of absorption is part of the mechanism. That would give an explanation as to the nature of the immunity; that is, the formation of some mechanism by which absorption does not occur. It is difficult to say why that should persist for one year. Another series of animals showed that in the beginning the reactions were the same. I think there must be vascular changes in the gastro-intestinal tract which would interfere with absorption. I have saved the lives of a number of animals by applying artificial respiration when convulsions occurred, because the clonic convulsions lead to asphyxia. The convulsions are so severe that the animals injure themselves. In the guinea-pig there are no true palsies, although there is incoordination following the convulsions. I have not noted any difference in the sex incidence.

Effect of Intravenous Administration of Quinidine and Other Drugs on the Mechanism of the Heart Beat

Dr. Frank N. Wilson, Ann Arbor, Mich.: I do not advocate the indiscriminate use of intravenous medication in heart disease. I believe that drugs can be given by mouth with less expense and trouble and with less danger. Nevertheless, intravenous medication has its advantages. I have given such drugs as quinidine, digitalis, pilocarpine and atropine intravenously. Quinidine has been given intravenously with very few reactions; sometimes there is slight blurring, confusion, a feeling of warmth, slight headache and nausea, but rarely vomiting. One patient died after a second dose. His was a case of advanced myocardial disease. Digitalis and ouabain differ from other drugs in that they penetrate the cells, but effect was obtained five minutes after injection. In paroxysmal tachycardia, digitalis given intravenously acts in a striking manner in lowering the ventricular rhythm and stopping the attack. With quinidine, if there is no reaction within seven minutes, there will be no reaction at all. Five out of thirty patients were benefited by quinidine intravenously.

DISCUSSION

Dr. G. C. Robinson, Nashville, Tenn.: I was interested that the intravenous injection of ouabain continued to be effective, but the maximal effect was not for several hours. The effect of large doses of digitalis by mouth is about the same as with ouabain intravenously. The intravenous injection of digitalis continues to be effective and is a gradual process.

Dr. Levin, Baltimore: Dr. Wilson's observations emphasize a point in regard to quantities, as to the margin of safety between a toxic and a therapeutic dose. This is small when the drug is given intravenously and is in the active circulation. Even when the drug is given by mouth, there is some evidence of poisoning in some patients. With more careful selection of cases we have limited the number of persons who receive this drug, and the percentage of successes is higher. With regard to the transition from fibrillation to normal rhythm, we found that in one instance, when the drug was given by mouth, the rhythm went back to normal with prompt resumption of auricular activity. I should like to ask whether in cases successfully treated by the intravenous method Dr. Wilson had tried giving the drug by mouth first in order to compare results with the slower medication.

Dr. Frank N. Wilson, Ann Arbor, Mich.: In regard to Dr. Levin's question, we do not give any patients quinidine by mouth or subcutaneously. We give the drug intravenously. The intravenous dose is really no more than half the dose by mouth. I do not know whether it is safe to go higher with intravenous dosage, although we had only one bad result, in a patient with advanced subacute bacterial endocarditis.

Observations on Patients with Pernicious Anemia, Partaking of a Special Diet

CLINICAL ASPECTS

Drs. George R. Minot and William P. Murphy, Boston: The dietetic treatment of pernicious anemia may be of more importance than has been generally recognized. Forty-five patients with pernicious anemia have continued to take a diet for from six weeks to two years, composed especially of foods rich in complete proteins and iron—particularly liver (from 120 to 240 Gm. a day). The diet also contains for each day at least 120 Gm. of muscle meat and an abundance of fresh vegetables and fruits, a normal amount of starch foods, and is relatively low in fat. Following the diet, all the patients showed a prompt, rapid and distinct remission of their anemia, coincident with at least rather marked symptomatic improvement, except for disorders due to spinal cord degeneration. Improvement was often striking, so that when the red blood cell count averaged for all, before starting the diet, 1,470,000 per cubic millimeter, one month afterward it averaged 3,400,000; and for the twenty-seven cases observed from four to six months after the diet was begun, the average count was 4,500,000. Patients having had two or more relapses showed on the average slightly lower red blood corpuscle counts about one and two months after commencing the diet than did those who had started it in their first or second relapse. Data are not yet available to indicate whether the remissions will last any longer than in other cases, because most of the patients have taken the diet for less than seven months. All the patients have remained to date in a good state of health except three, who discontinued their diet. Two of these rapidly improved on resuming it, while the other has only just begun to take the liver again.

PHYSIOLOGIC ASPECTS

DRS. REGINALD FITZ, WILLIAM P. MURPHY and ROBERT D. MONROE, Boston: Special studies concerning changes that have occurred in the blood following the beginning of the dietary regimen have been carried out in eleven of the forty-five cases. Within a few days after starting the diet, there occurred in the eleven cases and also in five others a temporary greater output of young red blood cells from the marrow, lasting about ten days, as indicated by an increase of the reticulocytes in the peripheral blood from usually less than about 1 per cent to an average of about 8 per cent. The peak of their rise occurred in from four to ten days. This early manifestation of improvement in blood formation was accompanied by a decrease of the bile pigments in the blood serum. The icterus index began to drop quite promptly after the diet was begun, generally reaching normal or below in from two to three weeks. The corpuscular protein content increased in a fashion closely parallel to the increasing hemoglobin concentration, while the plasma protein nitrogen readings remained nearly constant. The nonprotein nitrogen of the blood was not affected during the patients' improvement. As in other pernicious anemia cases regenerating blood, coincident with the rise in hemoglobin percentage and red blood cell count, there occurred a steady rise in the corpuscular volume. This was demonstrated by measurements of the blood and plasma volume by the congo red method, which showed that although the total volume increased but slightly, the volume of corpuscles often was trebled in a period of a few weeks, from which it may be interpreted that a marked growth of blood tissue was observed.

DISCUSSION

DR. W. S. THAYER, Baltimore: How long were these cases observed on an average, and how long was the longest case observed without remission?

DR. A. S. WARTHIN, Ann Arbor, Mich.: In 1895 a woman suffering from pernicious anemia was being treated by leading clinicians. She died thirty years afterward. For many years she lived on one apple a day and two or three bowls of weak coffee. At 76 she became senile and developed a huge appetite for meat. The picture of pernicious anemia disappeared, and she lived to the age of 86. Another woman who had pernicious anemia for twenty years ate nothing but lettuce. She had cord symptoms. She made a great change in diet and the pernicious anemia disappeared, but the cord symptoms remained and she was killed by a dose of arsphenamine. I believe there is a distinct relation between pernicious anemia and faulty diet.

DR. F. M. ALLEN, Morristown, N. J.: I have had patients with pernicious anemia who showed marked edema. They were put on a salt free diet, which improved the blood picture and the clinical symptoms. In general, improvement has been the same as in Dr. Minot's series. We considered that pernicious anemia was a metabolic disease due to infection of the blood forming organs, and we removed all foci of infection to give the blood forming organs a chance. We refrained from arsphenamine and from transfusion. I am favorably impressed by Dr. Whipple's work, but I am not sure as to the results of liver. It does not cure pernicious anemia. The blood picture can be recognized even when the blood count is improved. The nerve lesions are the hardest to clear up. In our experience, patients have died while taking liver. We have had patients give almost uniform results. The suspicion occurs to me that we are all alike in refraining from injuring the patient and if they can be spared from what physicians do to them they do better. It is not wise to force the patient to maintain too high a blood count. Transfusions may be used in acute emergencies and we may use arsenic, but not as a routine.

DR. W. M. BOOTHBY, Rochester, Minn.: Was the liver well cooked, moderately cooked, or raw?

DR. REGINALD FITZ, Boston: At the Massachusetts General Hospital we have seen very surprising changes in the blood count, but in one patient who would not eat the liver, there was no improvement.

DR. J. S. MEANS, Boston: There were an unusual number of remissions, much higher than before the diet. Patients did not do so well if they discontinued the diet.

DR. HERMAN O. MOSENTHAL, New York: The problem is this: There is something which destroys the red blood cells and it is our function to allow the body to regenerate the red blood cells faster than the toxic material can destory them. We should especially allow protein to build up the red blood cells; therefore, high feeding is effective. These patients are benefited by a high caloric diet. We have been able to control the number of red blood corpuscles. The nitrogen assimilation in pernicious anemia is different from normal, but feeding of protein will cause assimilation of nitrogen in these cases. In starvation after the war, and in diabetes, high protein feeding causes assimilation of nitrogen and improvement of the condition. Whether liver is the best high protein substance must be determined.

DR. GEORGE R. MINOT, Boston: Two of the patients had the diet two years, and twelve had the diet for over one year, the others less than eight months. In regard to diet playing a rôle: Patients often have been living on an ill balanced diet. In regard to the blood picture always remaining, as Dr. Allen said, I feel that this is always true. I know of two cases in which this is so. Dr. Boothby asked whether the meat was raw. It was well cooked. In regard to Dr. Mosenthal's remark, the changed metabolism is probably related to the amino-acids.

Effect of Ultraviolet Rays on Oxygen Consumption and Total Metabolism

DRS. EDWARD H. MASON, *Montreal, and* HOWARD H. MASON, New York: We used a quartz mercury vapor lamp without filter; it is not a pure ultraviolet ray. The cases were divided into two groups: first, those with a marked degree of pigmentation; second, those with an increased amount of circulating bilirubin, and therefore not any marked pigmentation. Group 1 showed marked reduction of heat production, pulse rate and metabolic rate. Group 2 showed increase in circulating bilirubin, as in catarrhal jaundice or pernicious anemia. This reaction may be the response of melanin in the skin.

DISCUSSION

DR. ALFRED F. HESS, New York: I should like to ask Dr. Mason whether he tried any effect with visible light because the source he used contained both visible rays and ultraviolet rays. Recent reports have shown increased metabolism; that is not in accord with a disease such as rickets, in which metabolism is slow and where ultraviolet rays are a specific. I have used melanin in suspension. If we added cholesterol and then melanin, the action of the rays could not be intensified, nor could it be done by adding tryptophane. We do not yet understand the relation of melanin to bile pigmentation. Dr. Mason says that he changed the wave lines. In what direction does he change them by a fluorescent substance? I do not think that melanin would change it in the same direction.

DR. GEORGE H. WHIPPLE, Rochester, N. Y.: In regard to the fluorescence of bilirubin, such material as we have studied does not fluoresce. I should like to know on what data Dr. Mason made that statement.

DR. E. H. MASON, Montreal: We have only used the total rays obtained from the mercury quartz vapor lamp. There were no pure filtered rays, and only the visible rays coming from the mercury quartz lamp were used. Clinical observations showed that ultraviolet rays tend to increase metabolism, but I think this is merely a clinical impression. As regards fluorescent substances, my opinion about the change of wave lengths along the path of a fluorescent substance was obtained from Professor Lloyd at McGill. I understood that there is a shift of the wave in the path of the light. He tells me that bilirubin is fluorescent and that the shift of the wave is appreciable. Probably it is shift of the heat wave.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

Archives of Internal Medicine, Chicago

37: 453-595 (April) 1926

*Mechanism of Cancer Metastasis. M. T. Burrows, St. Louis.—p. 453.

Gastric and Duodenal Ulcer. A. Winkelstein, New York.—p. 541.
*Therapeutic Use of Diets Low in Water and in Mineral Content. N. M. Keith, F. H. Smith and M. Whelan, Rochester, Minn.—p. 550.
Water Metabolism. H. E. Andrews, Chicago.—p. 559.
**Effect of Digitalis on Ventricular Premature Contractions.* H. L. Otto and H. Gold, New York.—p. 562.
Pressure on Central Nervous System in Relation to Hyperglycemia: Chronic Piqûre. W. Z. Tychowski and C. Crowell, Philadelphia.—p. 567.

Mechanism of Cancer Metastasis.—Observations are reported on by Burrows from which it is evident that metastases in cancer are not the result of a simple migration of cancer cells from the cancer to distant organs. Metastases are primarily the result of the spread of a liquid substance from the main tumor mass. This substance spreads over surfaces. It is liberated through a digestion of cells in the center of the mass of cancerous tissue. This digestion is not an autolysis resulting from the absence of oxygen, but the result of an excess of the growth stimulating substance, a product of the cell's oxidation. This fluid is rich in growth stimulating substance. It stimulates not only the cancer cells to grow but also the normal cells. The cancer cells already adapted to it respond more quickly. In their growth, they then remove the nutrition and necessary substances from the other cells and destroy them. As to the cause of cancer, these observations suggest that cancer is not the result of any specific substances or group of substances. It is the result of some primary change either in the cell or the tissue which may be induced by any one of a number of widely different substances and conditions.

Arteritis of Pulmonary Artery.—Chronic and acute arteritis of the pulmonary artery and of the patent ductus arteriosus has been observed in nineteen cases. To two of these cases in which no additional valvular lesions were found, a third is added by Schlaepfer. In all nineteen cases, the picture was that of a subacute bacterial endocarditis, with the signs of a patent ductus arteriosus. The seat of the arteritis is undetermined. The anterior wall of the pulmonary artery and the pulmonary orifice of the duct are the places of predilection.

Relationship Between Acromegaly and Diabetes.—Two cases are reported by John in each of which diabetes developed years after the acromegaly was recognized. They illustrate the fact that diabetes associated with acromegaly does not differ materially from diabetes without acromegaly; that the same treatment is applicable to the former as to the latter types of cases of diabetes; that in each, the same results may be expected under proper treatment, and that in each case, if the patient is untreated or is improperly treated, the same increased loss of carbohydrate tolerance, acidosis and coma ensues.

Use of Diets Low in Water and Mineral Content.—Keith and his associates have found carefully controlled diets of low mineral and water content both practicable and effective in the treatment of cases of edema and ascites. The diets may be varied in protein and caloric value, with little increase in mineral or water content. There have been no demonstrable ill effects from the continued use of these diets.

Effect of Digitalis on Ventricular Premature Contractions.—In a case reported by Otto and Gold, digitalis in full doses; given at once, completely abolished spontaneously occurring premature ventricular contractions. Three grains (0.19 Gm.) daily of the powdered leaf, for four days, failed to abolish them. They disappeared after a full dose in the time necessary for practically complete absorption of the drug. The same results were obtained on repetition. After the first full digitalization, seven days were allowed without digitalis for elimination of the drug; the premature contractions began to reappear on the third day. However, when a daily maintenance dose of 3 grains of the leaf was started immediately after the second full digitalization, the premature contractions did not reappear. The persistence of the effect after withdrawal of the digitalis was considerably longer following prolonged digitalization than after a single full dose.

Why Chronic Gonorrhea in Male? P. S. Pelouze, Philadelphia.—p. 464.

Glandular Treatment of Pituitary Hyperplasias.—The therapy applicable to pituitary hyperplasia, Timme says, is specific; namely, the administration of whole gland pituitary substance in very small doses, from ⅒ to ¼ grain (0.006 to 0.016 Gm.) once or twice daily, at least two hours after meals. Every fourth or fifth day the administration should be omitted. If too much extract is given, the headaches are made worse, or may even be brought on thereby. Should they be accompanied by mild hyperthyroid states, with low grade excitement and irritability, it is an excellent plan to give, in addition to the pituitary extract, hypodermic injections of sodium cacodylate, from ¾ to 1½ grains (0.04 to 1 Gm.), every alternate day for fifteen or twenty injections. An important point in the treatment is to discontinue the pituitary extract as soon as the premonitory signs of a headache make their appearance, and not begin again until the headache has disappeared. Of the various exciting causes, those which are remedial should be remedied—such as going without food too long, or indulging in too much carbohydrate food. By these simple means, many so-called chronic migrainous attacks of pituitary origin may be reduced to two or three yearly.

Roentgen-Ray Therapy of Pituitary Lesions.—Seven cases of pituitary lesions are presented by Grant as examples of the type of case in which roentgen-ray treatment proved effective in reducing the size of the tumor or checking its growth. Headache was not a prominent symptom in this series. In many of the patients, the condition appeared after the onset of the climacteric, so that it could not be determined whether or not this therapy might have resulted in a return of the menstrual cycle. In every case, the visual fields were enlarged, and the visual acuity increased. As was to be expected, there was no regression in the bony changes about the sella.

Surgical Management of Pituitary Lesions.—Frazier has made it a practice to resort to radiotherapy in all his cases after operation for its prophylactic effect, but without substantial evidence of any beneficial influence, except perhaps that since this practice has been introduced, no patient has returned to the clinic with signs of recurrence.

Treatment of Purpura Hemorrhagica.—The following procedures are recommended by Fitz-Hugh, and in the following chronological sequence for any given case of purpura hemorrhagica: (1) blood transfusions, to be repeated according to indications and effects; (2) massive irradiation of the spleen (this should be repeated unless leukopenia develops, which is a danger signal), and (3), as a somewhat heroic though decidedly promising procedure, splenectomy should be performed.

Treatment of Secondary Anemia.—Sheppard says that the administration of small doses (from 5 to 10 cc.) of whole blood, given intramuscularly every day or every other day, seems to be of decided benefit when other methods have failed. The use of transfusions is of questionable value, except in those cases in which the blood stream has been more or less rapidly depleted by hemorrhage.

Case of Erythema Arthriticum Epidemicum. K. Dodd, Boston.—p. 633.

Sacro-Iliac Disease.—Painter asserts that there is an overwhelming body of evidence to the effect that sciatica is a cardinal symptom of sacro-iliac lesions and that it is a perineuritis brought about by the proximity of the radicals making up the main trunk of the sciatic to whatever lesion is affecting the joint. Furthermore, the evidence, which is accumulating and which was, as a matter of fact, among the earliest pieces of evidence in support of the idea that there was a sacro-iliac joint, should tend to give pause in advocating operative measures, other than manipulative, in the treatment of traumatic sacro-iliac lesions.

Roentgenography of Chest.—A series of patients was studied by Monroe and Emery, Jr., to determine the best criteria for requesting roentgen-ray examinations of the chest in cases in which the physical findings or symptoms suggest pulmonary tuberculosis. The results tend to show that films should be taken whenever the symptoms suggest the presence of tuberculosis, and that the physical findings are less reliable guides.

Carbon Dioxide Inhalation in Empyema.—The usual methods employed to promote reexpansion of the lung are discussed by Churchill, and the use of carbon dioxide inhalation for its mechanical effects on the lung and thorax is described. As far as is known, there are no deleterious effects to be expected; in fact, the dizziness and other unpleasant subjective symptoms which are apt to attend too vigorous employment of other respiratory gymnastics do not occur with the use of carbon dioxide. Churchill uses the carbon dioxide inhaler as employed by Henderson in the detherization of postoperative cases. The tank is left at the bedside of the patient after he has been instructed in its use, and the duration and frequency of the exercise are varied to suit the needs of the individual case. The average ambulatory convalescent patient inhales the gas for five minute periods fifteen or twenty times a day.

Experiment in Medical Education.—The University of California Medical School has had the cooperation of some of the prominent alumni in the preparation of students for practice. These alumni have, severally, spent a week at the school carrying on, by seminar, lecture and personal contact, instruction in the art and practice of medicine. The experiment has proved of great value to students, interns and faculty alike, and the alumni have expressed themselves as well repaid for the time spent at the school. This year (1925) a further experiment was tried by Kerr during the second half, or the elective period, of the fourth year. Three selected students were apprenticed to alumni in general practice in communities of varying size and assigned for a month each. Another student spent a month in a group clinic in a small town in which there is close cooperation on all cases. Reports from these students give some idea of the value of such contacts for the undergraduate. The students and alumni have expressed themselves favorably on this method of instruction.

Surgical Judgment.—Fairchild asserts that every individual by law made eligible to operate should by law be required to keep records of his cases. These records he should be compelled to submit, on request, to the inspection of some competent constituted authority for review. This would work no hardship and could entail no embarrassment on the competent surgeon. It would strengthen and protect him. It is obvious what the effect on the incompetent and dishonest would be. His exposure would be inevitable and his ultimate downfall a certainty. The profession and the public have a right to know the truth. The factor of individual responsibility properly applied would be conclusive.

Carcinoma of Kidney.—Rusche says that, contrary to the formerly accepted opinion, carcinoma of the kidney is rare before the fifth decade. The mistaking of mixed tumors for carcinomas is responsible for the large number of these growths formerly reported as occurring in extreme youth. Carcinoma develops from the tubular epithelium, or occasionally from the epithelium of the pelvis. In some cases the urinary canals may, to a certain extent, persist, and if dilated, may form large spaces. The much discussed intracellular formations of cancer cells are well seen in these growths. Clinically, the neoplasm may be hard or soft, more often soft; it may become colloid and may form a fungoid vascular mass. It has been found associated with testicular carcinoma and (in the aged) with calculus. In a few cases, the growth has broken through the skin. Metastasis occurs most frequently to the retroperitoneal lymph glands, the lung and the liver. The tendency to produce hematuria is due to the infiltration of the tumors. The earlier metastases occur through the lymphatics; later, when the veins have been invaded, carcinomatous thrombi may be carried by these vessels.

Liver Function Tests in Eclampsia.—In Stephenson's opinion, there is no liver function test now available that is devoid of danger, easy of application, and at the same time reliable. Kidney function tests are better adapted for use in these toxemias. The readings, however, are not constant, and the demonstration of lowered function is more apt to come in cases in which some damage has been done to the vascular system in the kidney or in patients with preexisting nephritis. After the acute toxemia has subsided, they give much valuable information as to the function of the organ, particularly with reference to permanent injury. This information is of great importance in the prognosis for future pregnancies. Examination of the eye grounds should be made in all cases of acute toxemia. Blood chemical findings may be omitted with the possible exception of the blood urea. Blood pressure readings are important. A gradually increasing pressure, particularly diastolic, usually means an increasing toxemia.

Intestinal Obstruction.—Ninety-three cases of intestinal obstruction in which operation was performed with a mortality of 34.4 per cent were reviewed by Butler and Delprat. There were thirty-four inguinal hernias with obstruction; four umbilical hernias; four ventral postoperative hernias, and nine femoral hernias. All contained portions of the ileum. There were seventeen obstructions due to abdominal adhesions. Ten of this group were due to postoperative adhesions; one was caused by adhesions to the tip of Meckel's diverticulum; two were due to adhesions resulting from acute inflammation of the pelvic organs, and two were due to adhesions about the terminal ileum and cecum. Three obstructions were due to volvulus; one involved the small bowel, and two involved the sigmoid. Carcinoma accounted for eleven—two of the pylorus, one of the jejunum, three of the cecum, two of the descending colon, two of the sigmoid, and one of the rectum. Six enterostomies alone were performed in this group; one patient recovered. Resection of the cecum, followed by immediate anastomosis, was done on two patients; one recovered. Two patients had resections of the pylorus, followed by anastomosis; one recovered. On one patient, gastro-enterostomy for carcinoma of the small bowel was followed by death. In six obstructions, the cause could not be determined, because when the patients came into the hospital they were moribund, and enterostomy alone was performed.

Mongolian Idiocy.—Dietrich and Berkley report two cases, each occurring in one of separate sets of twins. The twin in each case was normal.

*Symptoms of Coronary Occlusion. L. Hamman, Baltimore.—p. 273.
*Arteriosclerosis of Cerebral Vessels; Pathogenesis of Hypertension. J. Bordley, III, and B. M. Baker, Jr., Baltimore.—p. 320.

Symptoms of Coronary Occlusion.—The symptoms of coronary occlusion described by Hamman are the symptoms that develop when a relatively large branch of the coronary arteries is obstructed, and the obstruction is followed by the development of an infarct. The symptoms are grouped as: (1) the immediate symptoms associated with the occlusion, the anginal seizure; (2) the symptoms associated with the myocardial damage, myocardial insufficiency; (3) the symptoms associated with the myocardial infarct, and (4) additional symptoms. It is emphasized that the diagnosis of coronary occlusion has something more than academic interest, since prompt recognition of the accident may promote recovery. Rest is a potent therapeutic measure; strain has a damaging effect. In coronary occlusion, the immediate outcome of the accident may depend on getting the patient promptly at rest, and the degree to which the heart will finally regain its functional capacity may depend on the length of time rest is enforced. Therefore, in some instances the fate of the patient may depend on the recognition of the accident. After the immediate danger is over and alarming symptoms have passed, prolonged rest insures the best possible functional restitution. Every week through which rest can be prolonged will improve the final functional result. To relieve the symptoms of the attack, morphine should be given in large doses. At the same time the patient should be promptly and fully digitalized. If digitalis has not been given previously, the appropriate dose of an efficient preparation should be calculated and administered according to Eggleston's method.

Arteriosclerosis of Cerebral Vessels and Hypertension.—Bordley and Baker are convinced that there is at least an association between persistent hypertension and arteriosclerosis of the vessels supplying the brain stem. As it has long been recognized that arterial hypertension is accompanied by arteriosclerosis in at least some portion of the body, they suggest that a localization of this process in the medulla oblongata may be the essential factor in the production of the persistent high blood pressure, although these changes may be secondary to the hypertension.

Estimation of Blood Calcium.—A colorimetric method for estimating blood calcium has been developed by Roe and Kahn which is based on the precipitation of calcium as phosphate, and the determination of the latter by the molybdic oxide colorimetric procedure. The method is said to be very accurate and is a successful micro procedure, being adaptable to much smaller quantities of serum than other methods in use at the present time.

Concentrated Antineuritic Vitamin Prepared from Brewers' Yeast.—A relatively simple method for preparing fairly large quantities of a highly active nonhygroscopic vitamin concentrate from brewers' yeast is described by Seidell. The several steps of the method are: removal of the yeast protein by boiling; absorbing the vitamin from the resulting solution by means of fullers' earth; extracting the activated solid with sodium hydroxide; acidifying and concentrating by vacuum distillation; removing the sodium as sodium sulphate and the nonactive organic material by means of methyl alcohol; finally, converting the active viscous residue to a nonhygroscopic dry powder by treatment with strong ethyl alcohol.

Determination of Urea by Autoclave Method.—A combination of the autoclave method of Folin and Wu for converting urea into ammonia, and the estimation of the ammonia thus formed by the technic of Pregl and the apparatus of Parnas and Wagner, are utilized by Clark and Collip in developing an accurate chemical system for the determination of urea in Folin-Wu blood filtrates. An electrically controlled modification of the Parnas-Wagner micro Kjeldahl apparatus is given.

Blood Sugar Studies.—Postprandial hyperglycemia was studied by Gilbert, Schneider and Bock on normal individuals. From fifteen to twenty-two blood samples were taken within a three hour period. The blood sugar time curves show wide fluctuations, and in many cases a secondary rise before a definite return to the fasting level.

Guanidine Theory of Parathyroid Tetany.—The urea and nonprotein nitrogen curves of untreated parathyroidectomized dogs have been determined by Collip and Clark. Similar curves have been obtained *following the injection* of certain guanidine compounds. The results obtained are opposed to the guanidine theory of parathyroid tetany.

Effect of Hemorrhage on Blood.—The effects of hemorrhage on the inorganic composition of serum and corpuscles have been studied by Kerr. A single hemorrhage, amounting to from one third to one half of the total blood volume results in a slight decrease in both sodium and chloride of serum, *and no significant change in corpuscles.* Repeated severe hemorrhage produces a greater fall of sodium and chloride of serum, and an increase in the inorganic phosphate. No *changes in the potassium, calcium or magnesium of serum* were observed. A large increase in the potassium concentration of the corpuscles occurred.

Laboratory Study of Urine.—The report is made by Keilty of the laboratory studies of urine from 162 patients examined by cystoscopy and ureteral catheterization. While he does not advocate the routine use of the cystoscope and ureteral catheter as one might a vaginal examination or the proctoscope, Keilty is sure that its more frequent use when the urine is studied bacterially would clear up an otherwise obscure diagnosis; it would eliminate the kidney or bladder as offenders, or would accurately clinch a diagnosis strongly suggested clinically.

Sedimentation of Erythrocytes. — Cooper asserts that increased rate in sedimentation of the erythrocytes occurs in diseases attended by tissue degeneration and destruction. Principally this included: (1) acute inflammations; (2) pregnancy, (3) tuberculosis, and (4) malignancy. The curve during the first hour, and the final cell volume, offer prognostic value. The cause of the increased rate is associated with a hypercholesterolemia as well as an increase in globulin and fibrinogen in the blood.

Biochemical Affinity of Metals.—Schamberg and Brown have not been able to demonstrate, *in vitro,* any specific affinity of metallic and metalloid elements for organic tissues or for germs. Although no selectivity could be demonstrated, elements known to be therapeutically active (excepting arsenic) are absorbed by tissues to a marked degree.

Liver Function Tests.—By means of a combination of tests Rubenstone and Tuft were able to carry out the icterus index, blood chemical findings, levulose tolerance and dye tests at one time, and thus gain information concerning the bile pigment excreting functions of the liver and also its carbohydrate and protein metabolic functions. The patient is prepared as for a levulose tolerance; on the same tray the calculated amount of dye contained in a syringe is also prepared. Blood is then withdrawn into two tubes, one citrated or oxalated, and one a plain tube. Enough blood is withdrawn to suffice for all these tests. Through the same needle the calculated amount of dye is injected. Immediately following this the patient is instructed to drink the levulose solution. Blood is then withdrawn from the vein of the opposite arm at thirty minutes, one hour, two hours and, if necessary, three hours after the injection, the blood being again drawn into plain and oxalated tubes as indicated. The blood is allowed to clot, is centrifugalized, and the serum is pipetted off. The serum collected before the injection is then used for the *icterus index determination and also as the standard for the* dye test. As a rule, from 2 to 3 cc. of serum is sufficient for this purpose. The oxalated blood collected before injection *is used for the urea nitrogen, nonprotein nitrogen,* and sugar determination. Blood sugar tests are made on all the bloods (oxalated) taken subsequent to injection, and the serums are used to determine the dye retention, as described in the Rosenthal method.

Culture Medium for Endameba Dysenteriae.—The most satisfactory medium for cultivating *Endameba dysenteriae* Kofoid and Wagener found to be the coagulated egg slant covered with 10 cc. Locke's solution, containing 0.5 per cent of defibrinated rabbit blood. This medium is less favorable to the bacteria, which are found with the ameba cultures and quickly lower the p_H, than either Boeck's *egg-Locke-serum* medium or his egg-Locke-albumin medium. It is also simple to prepare, as fresh sterile rabbit blood can be easily obtained. On this rabbit blood medium the endameba multiply rapidly and are frequently found ingesting rabbit erythrocytes. It is necessary to transplant the cultures every forty-eight hours in order to keep them going continuously.

Necropsy Findings in Diabetes.—An analysis is presented by Wilder of the pathologic conditions found in a group of eighty-one fatal cases of diabetes. Diabetes was solely and directly responsible for death in ten cases, death in the remainder being due to degenerative complications or to the consequences of operations. Necropsy was performed in fifty-eight cases. Gallstones were found in sixteen cases and pancreatic stones in three. Sclerosis of the kidneys occurred in fourteen instances, and chronic diffuse nephritis in four. Arteriosclerosis of considerable degree occurred in nearly all the cases, when the age of the patient exceeded 40. Gangrene accounted for fourteen of the eighty-one deaths and was associated with a high degree of coronary sclerosis and myocardial injury in 75 per cent of cases in which the heart was examined at necropsy. A very high incidence of advanced coronary sclerosis was encountered in the series as a whole (seventeen cases), associated, usually, with marked fibrosis of the myocardium. In four cases exophthalmic goiter and diabetes were combined. In two of these, the pancreas showed little or no anatomic abnormality. Hydropic degeneration was not recognized, but marked fatty changes in the islands occurred in eleven cases. In several cases, representing the most severe and intensive instances of diabetes in the series, the pancreatic lesions were trivial. On the other hand, severe pancreatic lesions were frequently found in cases of mild diabetes, in which death was due to degenerative complications. Wilder feels that the explanation of the cause of diabetes must involve considerations, such as heredity of predisposition and ability of cells other than those of the pancreas to elaborate insulin.

Elective Localization of Streptococci.—This experimental study by Haden shows that bacteria from chronic foci, if etiologically related to systemic disease, tend to reproduce in animals the lesion from which the patient suffers. Four groups of cases are reported in which a striking tendency to elective localization is demonstrated.

Irritable Colon.—M. L. and G. Graves assert that there is a large group of cases referred to in the literature as cases of chronic intestinal indigestion, dyspepsia, spastic constipation, hypo-acidity and neurasthenia, which it would be better to class as cases of irritable or disordered colon. These cases are more frequent among slender ptotic types of individuals. The pathologic change is intimately linked with the functional abnormality of the large intestine. The prognosis is good, except where there is an ulcerative process due to a chronic ulcerative colitis, to cancer, or tuberculosis or cases of dysentery, which often are very stubborn and difficult.

Prevention of Heart Disease.—The time to prevent or cure heart disease, Townsend says, is seventeen or more years before death from heart disease occurs. The means and the only means whereby the number of victims will be reduced is to pay conscientious attention to the little child with aching muscles who is accused of having "growing pains," the care of neglected and decayed teeth, the discovery and removal of all foci of infection whether of the tonsils, sinuses, intestines or what not, and repeated careful examinations of the heart, subsequent to attacks of any acute infectious fever, to discover what and how much that injured heart can stand. To accomplish this end, the full cooperation of the people must be secured and the degree of this cooperation will be determined by the degree to which they know the facts. Health education, in Townsend's opinion, is the remedy.

Sodium Chloride Treatment of Intestinal Obstruction.—Whatever the explanation of the chemical changes in the blood and urine may prove to be, Orr and Haden assert that the fact remains that there is a definite therapeutic benefit derived from the administration of sodium chloride in pyloric and intestinal obstructions, which tends to reduce the blood chemical determinations to normal and to prolong life.

Sodium Chloride Solution Intravenously in Extensive Burns.—In a case of very extensive superficial burns reported by Bigger, prompt and continued improvement followed the intravenous injection of 100 cc. of 20 per cent sodium chloride solution.

*Surgical Treatment of Intracranial Hemorrhage in New-Born. W. O. Ott, Fort Worth.—p. 721.
*Ovarian Hemorrhages. F. C. Beall, Fort Worth.—p. 724.

Heart Pain.—Baird has analyzed 100 cases in which the chief complaint was pain around the heart. The pain was caused most often by heart failure or myocardial weakness (forty-two cases); cardiac neurosis and hypertension each caused pain in seventeen cases; angina pectoris in fifteen cases; chronic endocarditis in seven cases and aortitis in two cases.

Intracranial Hemorrhages in New-Born.—Of the six cases reported by Ott, four infants were subjected to subtemporal decompression, one recovered after repeated lumbar punctures, and one required a suboccipital exploration with the opening of the foramina of Majendie and Luschka. Three babies are apparently perfectly well 21, 19 and 1½ months, respectively, after the operation; one recovered following lumbar punctures, and two died, one eight hours after operation, apparently from massive hemorrhage, and the other after living three months and eleven days after operation, this death occurring from a recurrent obstruction of the foramina of Majendie and Luschka. Ott emphasizes the importance of careful observation of new-born babies for development of untoward symptoms, such as respiratory difficulty, blue spells, muscular twitchings and convulsions, and refusal to nurse. New-born babies having such symptoms should be given 10 cc. of the father's blood, subcutaneously, and a lumbar puncture done. If the cerebrospinal fluid is blood tinged, repeated punctures should be performed. If the symptoms do not clear up under this regimen, a decompression operation is indicated.

Ovarian Hemorrhages.—Beall has seen three cases of massive hemorrhage from the ovary; two of these simulated extra-uterine pregnancies; the third caused obstructive symptoms. He says that without a careful histologic study of the ovary, an erroneous diagnosis of ovarian pregnancy might be made.

*Alveolar Abscess with Unusual Symptoms. E. D. Harrison.—p. 318.

Mercurochrome, Foreign Protein and Sugar in Gonorrheal Urethritis.—In 200 cases reported, as well as in animal experimentation, Potter and Redewill believe the results obtained prove that the milk injections intramuscularly activate intravenously injected mercurochrome-220 soluble. By the use of the diphenylcarbazide test for mercury in the seminal fluid and the mercurochrome kidney function test, it is possible, with the first intravenous mercurochrome injection, to detect patients that are not suitable for the continuous use of the drug By the Rackemann skin test, one can detect within fifteen minutes if a patient is sensitized to nonspecific foreign protein Milk and sugar, when injected alone, each have a diphasic action with a negative followed by a positive phase. Sugar added to milk alleviates shock, which may result if foreign protein is used alone. There are a number of disease conditions in which this treatment is contraindicated. If the cases are not properly selected in giving this combined injection, serious reactions may result In the animal experimentation, the combined use of mercurochrome, foreign protein and sugar cleared up staphylococcus infection more decidedly and in a shorter time than when either of the drugs was used alone Milk and sugar activate the mercurochrome, increase its bactericidal power, penetration, and permeability into the tissues, and stimulate a greater excretion of the dye from the glands, as is proved by the diphenylcarbazide and mercurochrome kidney function tests The most striking results are rapidity with which acute gonorrhea will respond to the combined mercurochrome-foreign protein-sugar treatment and the few complications that ensue.

Leukopenia.—Beers relates a case of Vincent's infection of the gums and tonsils in which the leukocyte count fell as low as 1,000 per cubic millimeter, polymorphonuclears, 12 per cent, lymphocytes, 68 per cent, and large mononuclears and transitionals, 20 per cent The symptoms complained of were cardiac pains and attacks of blindness.

Alveolar Abscess with Unusual Symptoms.—The onset in the case cited by Harrison resembled that of pneumonia; the symptoms suggested influenza, malaria or typhoid fever. Extraction of two teeth with large root abscesses gave immediate relief.

Active Immunization Against Tuberculosis.—The results of Enright's observations are such that he is convinced that attempts to immunize guinea-pigs with partly purified urinary antigens from cases of tuberculosis will have to be made on a scale large enough to rule out definitely the element of chance before it is desirable to make any interpretation of the results.

Actinomycosis of Pleura.—Shoemaker reports a case of *Streptothrix actinomyces* infection of the pleura One interesting feature of this case was the sudden development of a liver abscess after the patient had apparently entirely recovered from the chest condition. While it was not possible to demonstrate the actinomyces in the pus from the liver abscess, or after animal inoculation with this pus, the inference is that the later involvement of the liver was a metastatic process. At no time was the streptothrix demonstrated in the sputum.

Simple Ulcer of Small Intestine.—In neither of Bigger's two cases could the ulcer be attributed to any specific cause. However, in one case the presence of a prune seed near the site of the ulcer suggested trauma as a possible causative factor. Thirty-four cases of simple ulcer of the intestine are now on record.

"Stair" Sign in Early Tabes.—In Hodges' experience, the "stair" sign has proved valuable in the diagnosis of the early ataxic stage of tabes. The "stair" sign, which determines the patient's ability to descend properly a series of stairsteps, with eyes open, but not directed to his feet, or in certain cases, with eyes closed, thus at one time testing both the muscles and the joints, Hodges regards as one of the most delicate and definite tests of ataxia, and one that is often apparent before other signs of ataxia are evident.

Acute Glandular Fever.—From October, 1924, to May, 1925, a widespread epidemic of an acute infectious disease manifested by involvement of various groups of lymph glands occurred in the locality in which Carlson and his associates reside. There were at least 1,100 cases. The greatest number of cases appeared during January, February and March and had almost subsided the latter part of April. The epidemic was one in which many of the acute infections were present, such as septic sore throat, septic tonsillitis in many cases and acute glandular fever. The complications encountered were otitis media, peritonsillar abscess, nephritis and in one instance, erysipelas. Because of the mildness of the symptoms the disease ran its course unrecognized in many instances. Some of the cases were mistaken for a septic tonsillitis, a septic sore throat, all loosely designated as "grip," or classified as some other acute infection. During the last few years, there have been reported small epidemics of glandular fever in various sections of the country. The authors collected data on 838 cases. This group includes all of the cases reported during the epidemic. From this number they have selected seventy-nine cases which they classify as glandular fever. These cases are analyzed with reference to their clinical history. Acute glandular fever is considered by many as a distinct disease entirely, but the authors are of the opinion that the facts do not altogether justify its classification.

*Nephritis in Children: Prognosis. D. Paterson and W. G. Wyllie.—p. 103.
Tuberculosis of Childhood. A. Moncrieff.—p. 114.

Lambliasis as Cause of Chronic Enteritis.—Examination of twenty-three children infected with *Lamblia* has convinced Miller that the infection is by no means a rarity in hospital practice among children; that it produces a chronic enteritis; that the resultant diarrhea is often severe enough to cause the subjects of the disease to be considerably below their proper weight, and occasionally will produce retarded development and diminution of growth, suggesting that in lambliasis we have a further possible cause of infantilism of the enteritic type; that even in children true "carriers" may be found, infected with *Lamblia*, but without symptoms.

Prognosis of Empyema in Children.—The examination of thirty-six children from ten to thirteen years after operation for an empyema leads Smellie to the opinion that the remote prognosis is excellent. All show some evidence of scarring of the lung, but it is of negligible extent. So far as Smellie has been able to determine, there is no factor that will enable any forecast of the degree of this fibrosis to be made. The duration of the disease prior to operation gives no assistance, nor does the time required after operation for the healing of the wound; in fact, the average duration of symptoms before operation and the subsequent stay in hospital of Smellie's group showing no clinical fibrosis was practically identical with those averages obtained from the whole thirty-six cases.

Nephritis in Children.—Six deaths occurred among twenty-two cases of acute parenchymatous type, and one death, from other causes, among twenty-seven cases of acute hemorrhagic nephritis reviewed by Paterson and Wyllie. The importance of reexamination at an interval of years is emphasized by the difference in the conclusions which may be based on an immediate prognosis as compared with the results of later investigations. From a general examination the immediate prognosis seemed good in thirteen cases of parenchymatous nephritis and in twenty-six cases of hemorrhagic nephritis. After a period of from three to five years, only five of the parenchymatous patients could be said to have recovered completely, as compared with twelve recoveries in the hemorrhagic group. Six of the parenchymatous and nine of the hemorrhagic patients appeared to be in good health, but had albuminuria and abnormal cellular constituents in the urine. The degree of albuminuria and the quantity of cells present were definitely less in the hemorrhagic type than in the parenchymatous cases. Four out of six cases of postscarlatinal nephritis became chronic. The authors emphasize the importance in postnephritis of the presence of even a very slight trace of albumin when it is associated with an excess of cells in the centrifugalized deposit.

Recovery After Massage of Heart.—In the course of an operation for gastrojejunal ulcer, Ball's patient suddenly stopped breathing and his heart ceased to beat. His head was lowered and oxygen only was passed down the intratracheal tube under intermittent pressure. The stomach was rapidly separated, between clamps, from the duodenum and thrown over to the left side of the abdomen. The heart was then gently massaged through the diaphragm at the rate of about sixty to the minute, artificial respiration being kept up meanwhile; 10 minims of 1:1,000 epinephrine solution was injected into the heart muscle through the chest wall. Three minutes elapsed before any sign of heart movements was noticed, when a single forcible contraction was felt; this was followed by fibrillary twitchings for about ten seconds, and was then succeeded by a series of regular, rapid, feeble beats until gradually it beat with its normal rhythm, but at rather a rapid rate. Shortly after the heart began to beat, the patient commenced to breathe.

Gangrene of Leg in Infant.—Grove believes that the gangrene in his case was due to an embolus caught at the bifurcation of the anterior and posterior tibial arteries. The circulation was reestablished, except in the toes and sole of the foot. Only the toes were lost. As to the origin of this embolus, Grove suggests an abnormal umbilical artery on the right as the most probable source.

Scopolamine in Postencephalitic Lethargy.—Data supplied by McCowan, Harris and Mann show that in patients with postencephalitic lethargy, those with parkinsonian symptoms receive most benefit from scopolamine therapy, and that this clinical improvement is coincident with an "improved" blood sugar curve, which is made to approximate to the normal type. This improvement is due to a specific action of the drug, though suggestion may be a subsidiary factor. This action of scopolamine is only temporary, but prolonged use of the drug does not lead to tolerance or any deleterious effects. The hysterical element in this disease is probably due to lesions of the basal ganglions, and it is suggested that an analogous lesion may account for similar symptoms in hysteria, chorea, etc. Though in the majority of cases the full benefit of scopolamine can be obtained only by hypodermic administration, there is no doubt that in many cases considerable benefit follows its oral exhibition. The scopolamine may be administered either subcutaneously or by mouth. When given subcutaneously it seems to act more powerfully and its effects continue for a longer period than when the oral method is employed. The question of dosage is of some importance. It is best to commence with fairly small amounts and increase until the required effects are obtained. If given hypodermically, a start can be made with $\frac{1}{150}$ grain (0.4 mg.), once a day, and this amount can, if necessary, be increased until as much as $\frac{1}{50}$ grain (1.3 mg.) is being given once a day. When administered by mouth, larger doses may be given thrice daily, preferably just after meals, since if given before food the dryness of the mouth and throat makes mastication and deglution somewhat difficult and unpleasant.

Pressure by Mesenteric Root on Duodenum.—Robertson relates the case of a multipara, who on the fourth day following the birth of her last full-time child got out of bed and soon felt giddy. A severe headache followed, and was accompanied by severe vomiting. No pyrexia existed. These symptoms continued for four weeks. Vomiting was "propulsive" in type, of daily occurrence and was usually accompanied by headache but seldom by nausea. The vomit was partly digested food, and was occasionally bilious in character. By the end of a month the patient became very emaciated, and fits of a cerebellar type developed and became frequent. At this stage Robertson saw her, in consultation with her doctor. She was then considered too enfeebled for operation, and very soon she died. Necropsy showed (1) a tuberculoma, the size of a walnut, of the left cerebellum and (2) extensive tuberculous disease of the abdominal lymph glands. There was not a lymphatic area unaffected. Many of these caseous glands were as large as a small hen's egg; most were somewhat smaller. The mesenteric root was very thick and heavy with large caseous glands. There was not even a suggestion of "duodenal ileus."

Intestinal Obstruction by Gallstone.—Coldrey's patient had been treated from time to time by a physician for gallstones; because her general condition was very poor, no operation had been advised. She had had typical attacks of gallstone colic, clay-colored stools, and dark urine. Then symptoms developed suggesting acute intestinal obstruction, but before an operation could be performed, the woman passed by the rectum a huge gallstone, 2 inches (5 cm.) long and just over 1 inch (2.5 cm.) through, and barrel shaped.

Mercurochrome in Treatment of Malaria.—In six cases of malaria, Dundas and Telang injected mercurochrome-220 soluble, in 1 per cent solution, intravenously, the actual dose varying with the patient's weight, and being approximately 0.003 Gm. per kilogram of body weight. It had no effect on the malarial parasites, even after two doses. Stomatitis and ptyalism were marked features in every case. The drug appears to irritate the kidney tissue to the extent of producing mild nephritis.

Indian Digitalis.—Chopra and De found that digitalis leaf of good quality grows in the valley of Kashmir (northern Himalayas) and at Mungpoo (eastern Himalayas). Improvements in methods of drying and storage are recommended to get a uniform quality.

Belladonna in Intestinal Obstruction.—Pande cites twenty-seven cases of intestinal obstruction, acute and chronic, not advanced to the stage of ileus, in which he gave tincture of belladonna, in 30 minim (1.9 cc.) doses, every hour, till physiologic symptoms appear, when physostigmine and pituitary extract are exhibited if the intestines do not start acting. In a certain proportion of cases, in which the intestines did not act of themselves, in order to start their action, enemas of soap suds in lukewarm water were given frequently, and also at intervals high rectal enemas to which a liberal amount of castor oil or sweet oil is added. This facilitates the easy passage of a hard fecal mass which may be acting as a plug. If the belladonna is not well tolerated owing to extreme sensitiveness of the stomach, hypodermic injections of atropine should be first started and then followed by belladonna by the mouth, which is the route that is generally followed.

Night Blindness Caused by Ascaris.—In Harigopal's case, the patient, aged 6, became blind directly after sunset each evening, while if he left a brightly lighted room for a darker passage, he had to grope his way. There was no history of any serious illness, and no evidence of hereditary syphilis. There was a history, however, of his having passed worms, and of grinding of the teeth during sleep and of convulsions at the age of 2 years. Accordingly santonin and calomel were given, followed by castor oil. A large number of roundworms were passed, after which the night blindness cleared up completely.

Embolism of Spinal Cord.—Chacko's patient had an inflamed varicose vein from which it was evident that septic emboli were lodged in the spinal vessels; causing a complete paraplegia. The infected embolus set up an acute myelitis.

Osteomyelitis of Fifty-Six Years' Duration. G. B. W. Walker.—p. 908.

Visceral Pain and Referred Pain.—Ryle discusses pain associated with disease of the hollow viscera. He asserts: (1) that there is a true visceral pain felt by the viscus; (2) that visceral pain is due to an abnormal increase in the tension of the muscular element of the wall of the viscus, this increased tension resulting either from contraction or from a failure on the part of the muscle fiber to relax adequately in the presence of increased intravisceral pressures; (3) that visceral pain when occurring alone, or dissociable from attendant somatic pains, may be accurately localized by the patient; (4) that referred somatic pain and tenderness, e. g., the viscerosensory reflexes, and the associated visceromotor reflexes, although they may accompany a severe visceral crisis of mechanical origin, more frequently express an inflammatory lesion of the viscus, and (5) that, when persistent, they invariably express organic disease of the viscus of an inflammatory kind.

Cholecystogastrostomy for Peptic Ulcer.—Braithwaite considers cholecystogastrostomy as the operation of choice for inaccessible gastric ulcer. Cholecystogastrostomy brings only bile into the stomach; it obviously does not bring in pancreatic or normal duodenal fluid; thereby the undoubted beneficent effect of bile alone is proved, and it may be more than a simple reduction in acidity; bile may have other powerful qualities in the reduction of gastric disturbances. Braithwaite has done eighteen of these operations, sixteen for gastric ulcer in which excision or destruction of the ulcer was impossible or would have been very dangerous, one for a recurrent, intractable duodenal ulcer, and one for a hyperchlorhydria and pyloric spasm with typical duodenal symptoms. In the two latter cases, a cholecystoduodenostomy was performed just beyond the pylorus. Four patients are in the hospital now; results in the other cases have been most encouraging. No single patient has suffered in any way from the flow of bile into the stomach. In fact, there is nothing whatever to show that anything unusual has been done.

Ischemic Necrosis of Heart.—Bulmer and Lamb report the case of a man, aged 27, whose death, after a typical subacute or chronic nephritis with frequent acute exacerbations, was clinically due to coronary occlusion, and was diagnosed as such. At necropsy, the picture was that of subacute nephritis with a generalized arterial degeneration of a fatty type, with a terminal thrombosis of the left coronary artery at the site of an atheromatous ulcer.

Effect of Ultraviolet Rays on Tissues Grown in Vitro.—It appears from Moppett's study that various normal and malignant tissues have different powers of resistance; the kidney is the most sensitive, the heart next, and the spleen cells, which may be regarded as comparatively undifferentiated, require a lethal dose approaching that for sarcoma. The malignant tissues, however, are definitely more resistant to ultraviolet rays than normal tissues when grown into vitro in this way.

*Urea and Secretion Index with Hypertension. Richard and Roesch. —p. 380.

The Urea and Secretion Index in Cases of Hypertension.—Richard and Roesch list the findings with the Ambard coefficient, the urea content of the blood, and the record of the diastolic and systolic pressures over long periods of time. In 23.4 per cent of their thousand patients with high blood pressure thus investigated, the Ambard coefficient was normal. This percentage would be 55.2 per cent if all coefficients below 0.100 were accepted as normal. Determination of the urea content of the blood alone is no criterion for the functioning of the kidneys.

Treatment of Hemogenia. P. Merklen and M. Wolf.—p. 572.

Chronic Rheumatism of Tuberculous Origin.—Harvier, Rachet and Lemaire's patient, aged 40, developed chronic rheumatism after three acute attacks, twenty-three, four and three years before. The affection was located in the shoulder and limb joints. Roentgenograms demonstrated lesions of the joints and bones. Repeated bronchitis and anal fistula were among the signs suggesting the diagnosis of tuberculosis, and inoculation of guinea-pigs with the effusion from the knee joint induced in them a tuberculous process.

The Blood Sulphur in Melanoderma with Cirrhosis.—Loeper, Decourt and Ollivier emphasize that the sulphur content of the blood increases in bronzing cirrhosis as well as in Addison's disease. The sulphur is retained in the liver; considerably more sulphur is found in the portal vein than in the suprahepatic. The liver also retains amino-acids. Sulphur and amino-acids are carried to the liver from the intestine, where they originate from the food; they are carried also from the spleen, as a product from hemolysis. Sulphur and amino-acids compose the melanin. The liver receives also iron from destroyed red corpuscles in the spleen or blood. The three substances are oxidized, retained or destroyed in the liver. This functioning is disturbed in the pathologic liver, entailing accumulation of these substances and simultaneous appearance of melanin and iron pigmentations. Hence, the bronzing from the suprarenals and that with hepatic cirrhosis are induced by a similar process.

Vital Capacity in Heart Plus Lung Disease.—Caussade, Guillaume and Evrard measured the vital capacity of seven subjects with heart and lung disease. It was done during maximal exhalation of air into a spirometer, following a maximal inspiration. The coefficient of vital capacity appeared decreased in all. The reduction paralleled the pathologic process, also the course of the disease. The vital capacity was lowered with complications; it rose under the influence of treatment. Evidently the vital capacity may reveal an improvement in the heart and lung functioning, serving as a kind of barometer.

Favorable Action of Roentgen Rays on Hemogenia.—Goia used the treatment in a grave case of hemogenia, the so-called false hemophilia. The rays were applied to the spleen for fifteen minutes, and the bleeding from the nose and gums stopped the same day. The bleeding time, at the right ear, dropped from 105 to thirty-five minutes; at the left ear, from ten to five minutes. The general condition was notably improved by the fourth day; the ecchymoses and petechiae tended to disappear; the bleeding time at each ear was three minutes. The patient recovered completely in ten days. Examination of the blood showed only a few blood platelets. This seems to prove that not thrombopenia, but other factors are responsible for the hemogenia, especially endothelial lesions of the vessels. The favorable action of the roentgen rays may be ascribed to their distant influence on the endothelial cells of the vessels, since these cells are part of the system to which the reticular tissue of the spleen belongs.

Night Cough in Chronic Infectious Endocarditis.—Hatzieganu, Telia and Daniello call attention to paroxysms of coughing occurring always before midnight in patients with slow infectious endocarditis. They found the cough symptom in 80 per cent of their cases. It seemed to precede any clinical sign of heart insufficiency, its intensity corresponding to the fever. Exaggeration of the cough was sometimes observed before reappearance of fever. Specific recurring bronchitis accompanying the endocarditis may enhance the irritability of the *intrapulmonary nerve* terminals. This is favored by the recumbent position.

Mental Derangement with Spirochetal Jaundice.—In Hesnard's case the disease started with chills and dizziness, followed the next day by epileptiform convulsions and contractions. These meningeal symptoms vanished as soon as the jaundice appeared, two days later. Uremia with oliguria developed the fourth day, accompanied by a delirious form of mental confusion. This continued until death, the eleventh day. The mental disturbance in this case was evidently due to kidney insufficiency, complicating insufficiency of the liver.

*Retrogasserian Operation for Facial Neuralgia. L. Christophe.—p. 289.
Oscillometry in Obstetrics. Gosselin.—p. 293. C'cn.

Operative Treatment of Facial Neuralgia.—Christophe severed the sensory root of the gasserian ganglion in a man who had suffered from ophthalmic neuralgia of the trigeminus for ten years. The last four years the painful paroxysms had occurred as often as four or five times a day. The operation (February 20, 1926) was performed after all measures, including alcohol injections, had failed. The pains of the major neuralgia disappeared at once and permanently. Cutting the retrogasserian motor root entailed only slight disturbance in mastication, but there is still a mild neuroparalytic keratitis which is improving.

Vichy Treatment of Diabetes. G. Monod.—p. 380.

Influence of Climate in Treatment of Tuberculosis.—Bernard specifies that an altitude of from 1,000 to 1,200 meters, above sea level, is most suitable for the sojourn of the tuberculous. At this height, the air is pure, dry, and sudden changes of temperature are less likely to occur. The air at this altitude exerts a tonic action and suits perfectly patients with slight fever and minimal or moderate lesions. It is not favorable for those with persisting high fever or tendency to hemoptysis. An altitude of from 1,500 to 1,800 meters may have too stimulating an action, entailing increase of fever, sleeplessness, and respiratory and digestive disturbances. Humidity is not borne well by the tuberculous; nevertheless, humidity from rain and fogs seems to do much less harm than that from damp clay ground. Wind is of all atmospheric conditions the most injurious for the tuberculous. While sea air has a beneficial action on the tuberculous, seashore air may do harm, since atmospheric changes occur there frequently. Quiet, stable atmospheric conditions should be sought.

Mineral Water Treatment in High Blood Pressure.—Cottet emphasizes that the action of mineral water treatment may depend on the way in which it is used. Carbonated baths influence the arterial vasodilatation, the peripheral as well as the central, by way of certain skin reactions. They reduce the arterial tension, and stimulate the heart functioning. Drinking mild mineral waters stimulates kidney functioning, enhancing diuresis. The bath treatment will be more important in cases with high blood pressure chiefly associated with heart disturbances, while oral use of mineral water will be preferable, for instance, in Bright's disease with uremia.

High Frequency Currents in Treatment of Cervical Metritis.—Flandrin and Schil report the results of a year's work in this line. Surgical diathermy was applied in cases in which the cervix appeared enlarged, soft, the mucosa protruding and the process discharging. The active electrode was applied directly to the ulceration in the cervix. The sittings were brief, and were repeated at intervals of a week or two. After each sitting a picric acid dressing was applied for a day; then hot douches twice a day. After from three to six sittings, the outline of the external cervical orifice became normal, the ulcerations disappeared. The cervix was supple and permeable. Leukorrhea gradually improved. Electric sparking was employed in resisting and recurring ulcerations with slight eversion of the cervix and a profuse mucopurulent discharge. The electrode was applied at a short distance from the lesion, once or twice a day. Brush discharge was used as an adjuvant or alone in recent lesions. The high frequency currents did not cause any pain; anesthetics were never required. Cases in which amputation of the cervix seemed to be inevitable were cured by this method. Ten or eleven women were reexamined after a year. The clinical recovery had persisted in all. One of them became pregnant soon after the treatment, and delivery was perfectly normal.

*Hiccup in Tuberculous Meningitis. L. Langeron et al.—p. 455.

Palm-Chin Reflex in Facial Paralysis.—Radovici and Marinesco called attention in 1920 to a skin reflex, the palm-chin reflex. Irritation of the palm of the hand with a needle may be followed by rising of the corresponding half of the chin. This facial reflex was found in 60 per cent of normal subjects. Tests were made on twenty-five patients with facial paralysis and eleven with hemiplegia. Persistence or exaggeration of the palm-chin reflex, *on the affected side*, suggests a central origin for the paralysis. Absence of the reflex on the affected side, and its presence on the sound side are symptomatic of peripheral paralysis. Existence of the reflex on both sides, in a patient with facial paralysis, testifies to a central origin of the affection. Absence of the reflex on both sides has no diagnostic value, since this may occur also in normal persons.

Localization in the Spinal Cord of Hiccup Lesions.—Langeron, Dechaume and Petouraud describe a case of tuberculosis of the lung, with terminal meningitis, myoclonus and persisting hiccup. The microscopic findings showed that the tuberculous meningitic lesions were predominantly located in the cervical segment of the spinal cord, especially in the motor zone, where the phrenic nerve originates. The medulla presented only signs of inflammation, and was free from specific lesions.

Metatarsophalangeal Dislocation of Toes. E. Mourgue-Molines and J. Vidal.—p. 26.
*Sympathectomy for Peripheral Tuberculosis. R. Fontaine.—p. 53.

Periarterial Sympathectomy for Surgical Tuberculosis.—Fontaine applied the operation in six cases of bone, joint or skin tuberculosis. Considerable amelioration, with tendency to recovery, was manifest in a case with suppuration and fistula of the wrist, also in a rebellious lupus of the face and leg, with lesions of the tarsal bones. Elimination of sequestra became more rapid, and suppuration stopped after the operation. In one case the sympathectomy was combined with resection of the bone. The operation failed in three recent cases of bone and joint tuberculosis. The consecutive vasodilatation may have favored the growth of tubercle bacilli.

Gland Fever and Kidney Complications. P. Gautier.—p. 190.

Chronic Polyarthritis in Congenital Syphilis.—In Nobécourt's patient, a girl aged 15, the joint affection had started four years before, involving gradually the joints of the knees, ankles, wrists and hands. The lesions were bilateral and symmetrical, accompanied by atrophy of adjacent muscles and swelling of corresponding glands. The Wassermann test was positive in the blood. Under arsenical treatment the girl recovered; the joints became normal, the Wassermann test weaker. It is possible that joint lesions with congenital syphilis may be due not only to a local action of the spirochetes, but also to a general dystrophy. Nothing to indicate derangement of function in any endocrine glands could be incriminated in this case.

Acute Cerebral Tremor in Young Children.—In two of Wieland's three cases the tremor appeared after pneumonia; it was mild and without fever. The third case occurred after a gastro-intestinal affection, and was accompanied with fever and signs of cerebellar ataxia, especially a general hypotonia. There were no changes of mental or sensory character, no paralysis or spasms. It was a general intention tremor, most marked in the hands and feet; it decreased during rest, and disappeared in sleep. The children were about 3 years old; they recovered within a few weeks or months, without sequelae. The lack of cerebral or pyramidal symptoms suggested an extrapyramidal lesion, entailing a transient disturbance in the tract which controls the balance and synergy of the muscles. There are evidently vascular lesions induced by an infection. He has collected from the literature thirty analogous cases of benign cerebral tremor without signs of compression, all with recovery in a few weeks or months.

Pigmented Tumor of Spinal Cord. N. Ringertz.—p. 451.

Peculiar Familial Affection of the Nervous System.—Roussy and Lévy describe an affection observed in seven members of a family (two sisters, a brother and four children). The age of the patients ranged from 2 to 38. Unbalanced movements in the gait and in the erect position, general abolition of tendon reflexes, and bilateral or unilateral club foot formed the main symptoms. There were no cerebellar symptoms or changes of sensibility, no muscle atrophy or scoliosis. The cranial nerves appeared intact; nystagmus was never noted. The speech and mental faculty were undisturbed. The affection first became apparent as the children started to learn to walk, and no progressive tendency was apparent. The affection evidently differs from Friedreich's disease or the Charcot-Marie type. It appears as a morbid entity, with an unknown etiology so far. Congenital syphilis should be borne in mind. The lesions seem to be located in the posterior and lateral columns of the spinal cord, or in ganglion cells connected with the anterior horns.

Art as Form of Psychotherapy. H. Schwerdtner.—p. 345.
Complementary Enterostomy. R. Hoffmann.—p. 346.

Changes of Birds' Thyroid.—Haecker found at Halle large thyroids in crows shot during fall and winter (left lobe, maximum 41.6 cmm.). The glands were small in spring and early summer (minimum 5 cmm.). There were also histologic changes. The crows shot at Davos in April had larger thyroids than at Halle.

Injury of Eye from Infra-Red Rays.—Vogt produced grave injuries of the lens, retina and choroid by short infrared rays. Ultraviolet rays damage only the conjunctiva and cornea.

Constipation and Endocrinology.—Oswald emphasizes the frequency of hypothyroid constipation. Substitution therapy has excellent results. In other cases, injections of pituitary preparations may aid. He attributes spastic constipation to hyperthyroidism.

*Mishaps with Local Anesthesia. R. Riccio and F. B. La Rossa.—p. 85.
Angioma in Thigh. A. Biancheri.—p. 101.

Thyroid Grafting.—Boattini implanted scraps of thyroid tissue after partial or total thyroidectomy in rabbits, rats and dogs. These and his previous experiments confirm the possibility of the healing in place and persistence of function of homoplastic grafts of thyroid tissue. The graft heals best and becomes more abundantly and completely vascularized when implanted in the subcutaneous tissue of the abdomen.

The Trachea as Plastic Material.—Leone reports the successful use of a segment of a trachea to bridge a complete gap in an artery. The lumen of the trachea persists almost intact, reducing the tendency to thrombosis to the minimum. The arterial endothelium proliferates so abundantly that the junction is soon a solid union, and the endothelium crowds out the mucosa lining. The trachea retained its vitality, and the perichondrium even displayed a certain proliferative tendency.

Total Cystectomy in Women.—Cassuto extols the advantages of evacuating almost the entire contents of the small pelvis, from the rectum to the pubis. The ureter stumps are sutured to the skin, brought out through the rectus muscles. The patient must be adequately prepared for the intervention, first diverting the urine with a high lumbar fistula. He attributes to the lack of this preparation the fatal outcome in the one clinical case in which the method has been applied to date. The patient had uremia and an unfavorable Ambard index besides her bladder cancer.

Mishaps in Local Anesthesia.—Riccio and La Rossa discuss the share of procaine and of epinephrine in the untoward by-effects. They have found records of slight collapse in seven cases, tachycardia in two, a rise in temperature (to 39 C.) in six, headache or vomiting, two each, and intense agitation in three. A postoperative necrosis developed in fourteen cases, and secondary hemorrhage in fifteen. Fifteen fatal cases have been recorded. They incriminate the epinephine for nearly all these mishaps, and in particular for the fatalities with thyroidectomy and tonsillectomy. With hypertension, the additional rise under epinephrine may arrest the heart action.

Creatinine Excretion. V. Tripputi.—p. 415.
*The Pirquet Test and Vaccination. L. Ricciardi.—p. 421.
Encephalopathies. A. de Capite.—p. 426.

The Dick Test.—Giuffrè prepared toxins from streptococci of various sources (erysipelas, pus, etc.). They produced skin reactions in about the same percentage of normal subjects as has been found in America when using Dick's toxin. He had occasion to use his toxins in twelve subjects before, during and after scarlet fever. In three of them the results were constantly negative. In seven, the positive reaction turned to negative and remained so. In two, this negative reaction again changed back to positive.

The Pirquet Test and Vaccination.—Ricciardi found that tuberculous children develop tuberculin anergy, or at least a weaker reaction during vaccination against smallpox.

Proteins in Relation to Liver Disease. P. Farreras.—p. 16.

Pituitary Treatment of Asthma.—Buendia explains on a neurohormonic basis the action of pituitary extract in permanently curing or materially relieving fully 70 per cent of his cases of asthma. His series includes some that had been refractory to epinephrine and all other measures, and some of twenty years' standing. This treatment has the advantage over epinephrine that high blood pressure is not a contraindication for it. He injects subcutaneously 1 cc. of the extract of the posterior lobe.

Anatoxin in Immunization Against Diphtheria.—Ponce de León states that the mortality of the 5,903 cases of officially recorded diphtheria in the last seven years in Uruguay was 11 per cent. This formed from 0.02 to 0.09 per cent of the total mortality. He became convinced of the efficacy and harmlessness of anatoxin by experiments on guinea-pigs and horses. Ramon's technic was not strictly followed, as he could see no difference in the effect when only 1.5 per thousand of the formaldehyde solution was used, and the fluid kept only at 37 C. for thirty or forty days (Ramon uses a 3 or 4 per thousand solution and heats to 40 and 42 C.). Of 400 children under 12 given the Schick test, 48 per cent responded with a positive reaction. These were injected in the thigh with 0.5 cc. of the anatoxin. In twenty days the Schick test was positive only in 78 per cent. These were then given a second injection of anatoxin; twenty days later only 2 per cent responded positively, and these became negative after a third injection. The local reaction was practically absent. He found that the anatoxin retained its potency unimpaired for six or eight months at least.

Radium Treatment of Ozena.—Casterán relates that all the symptoms subsided in the ten cases of ozena reported in which radium had been applied to the nasal fossas, according to Vasilia's technic. In one case the ozena was of ten years' standing.

Blocking the Superior Maxillary Nerve.—Ubaldo Carrea gives nine large roentgen-ray pictures showing the exact technic for blocking the trunk of this nerve by introducing *a long fine straight needle through the posterior palatine* canal to the pterygomaxillary fossa. This technic avoids large vessels and anesthetizes the entire region supplied by the superior maxillary.

Cantani's Sign of Aneurysm of the Descending Aorta.—Even before roentgenoscopic examination, Adorni was able to affirm the existence of the aneurysm from the fact that the heart sounds could be distinctly heard on auscultation of the spine from the second dorsal vertebra to the first lumbar. They could be heard also but less distinctly along the left paravertebral line, from the third to the eleventh dorsal vertebra. The heart sounds could not be distinguished in the supraspinous and infraspinous fossas nor on the right paravertebral line. Cantani called attention in 1922 to the transmission of the heart sounds to the spine as an early sign of aneurysm of the descending aorta.

Feeding by the Rectum.—Boas feels that rectal feeding has been overestimated. Only the rectal administration of large amounts of water has proved dependable. The carbohydrates added to the water are more ornamental than nourishing. Yet they make the patient feel better.

Predisposition to Ulcers.—Strauss emphasized fifteen years ago the importance of a predisposition to chronic ulcers of the stomach. Local ischemia—mechanical, from the sagging stomach, as well as spastic, may account for part of the pathogenesis.

Skin Sign in Gastric Cancer.—Brandenburg used a weak solution of potassium permanganate, in a short glass cylinder, 3 cm in diameter, pressed water-tight on the skin of the forearm. He dipped in it the negative pole of a 1 milliampere current. After five minutes, he noted about twenty or thirty brown spots when the temperature of the solution was 20-24 C. If the temperature was 40-50 C., the whole field was covered with a fine deposit. With cold water, only a few coarse spots were visible. Scratching of the skin interferes with the experiment, because the current selects the scratch line. In several cases of cancer, the picture obtained with tepid or hot water resembled that with cold water in the normal subjects. The cachectic tuberculous, and patients during chills, reacted as in the cancer cases. Pernicious anemia and myeloid leukemia reacted the opposite way. Persons with rheumatic insufficiency of the aorta responded to cold like the normal to hot water. In the course of similar experiments, he found it advantageous to apply tincture of iodine to the parts of skin from which he took electrocardiograms. It diminishes the resistance to the electric current.

Idiosyncrasies of the Eye.—Fehr calls attention to conjunctivitis caused by hypersensitiveness to various drugs applied locally. The atropine catarrh causes a swelling of the follicles, edema of the eyelids and dermatitis. The eserine catarrh is milder. Procaine is not infrequently a cause. The condition may resemble erysipelas.

Carbohydrate Cleavage in the Liver.—Wohlgemuth and Sorochowitsch found that the surviving liver tissue of pancreatectomized dogs retains for a time the ability to form acetaldehyde from various carbohydrates. Later on, this faculty disappears. Insulin does not restore it.

Electrometric Stomach Tube.—Unger describes a stomach tube provided with a small copper-zinc element. He measures with a milliamperemeter the current generated. The strength of the current depends chiefly on the acidity of the gastric juice.

Blood Sugar in Dermatoses.—Simon found in psoriasis and furunculosis a higher level of blood sugar. Hyperglycemia is common in eczema, especially in chronic cases. Insulin treatment acts favorably sometimes, especially on the itching.

Cross-Bar Symptom of Gastric Ulcer.—Fränkel makes about ten roentgen pictures of the stomach within twenty seconds, draws the outline of the shadows, and superposes them. A short line (about 8 mm.) on the lesser curvature, without any signs of peristalsis constitutes this "cross-bar (*Riegel*) symptom." It is due to the local inhibition of the transverse musculature produced by an ulcer or (rarely) by a beginning carcinoma. A large percentage of such patients suffered a perforation. He regards it as the second direct reliable sign of gastric ulcer. The first sign was Haudek's niche.

Fractional Analysis of Stomach Content.—Isaac-Krieger concludes that the fractioned aspiration of gastric contents constitutes no advantage for the clinical study of the case nor for the diagnosis.

Roentgen Study of Male Urethra. H. Bronner.—p. 180.

Tumors of Mediastinum.—Braun reports two instances of removal of tumors from the posterior mediastinum. Artificial pneumothorax made on the day before the operation reduced the tendency to shock.

Skin Sensibility in Umbilical Hernia.—Stahnke found degeneration of the axis cylinder in the nerves of the skin *covering umbilical hernias. This accounts for the lowered* sensibility. If the myelin sheath degenerates, the anesthesia is complete. The degree of the changes depends on the extent and duration of the stretching of the skin.

Talma's Operation.—Tempsky reports on twenty-five cases of the Talma operation made at Küttner's clinic since 1901. A remarkable improvement followed in seven patients (28 per cent). Five in this group had hypertrophic cirrhosis, one atrophic cirrhosis and one ascites from cardiac cirrhosis.

Bone Marrow and Regeneration.—Willich concludes from his experiments with free autotransplants of bones in dogs that the endosteum and the bone marrow are just as important in bone formation as the periosteum.

Latent Syphilis.—Kolle and Evers inoculated rabbits with syphilis about four weeks after an injection of a bismuth suspension. The animals developed no symptoms. If the bismuth deposit was removed two or three months later, typical chancres developed. Other animals could be infected by inoculation of an emulsion from the popliteal lymph nodes of rabbits in which the syphilis was kept latent by bismuth. Experimental transmission of syphilis succeeds apparently in only 90 per cent of the animals, and only in a small percentage in direct transmission from man. Yet the popliteal lymph nodes of such apparently resistant rabbits are infectious. In one case, the chancre became manifest after inoculation with lymph nodes from an apparently immune rabbit that had been inoculated with the nodes from another rabbit which did not react. All this shows a close parallelism between the infection of rabbits and of man.

Estrual Reaction in the Blood.—Loewe, Lange and Faure publish their method for extraction of the estrual hormone from blood, urine and other fluids. They dissolve it in oil and inject in mice. They recommend a determination of the percentage of squamous cells without nuclei in the vaginal smears.

Degkwitz' Measles Serum.—Kochmann injected Degkwitz' measles serum in nineteen children. Only six of them did not get measles—chiefly because they were probably already immune. Two of the injected children died. One of these had been injected between the seventh and the ninth day of incubation, which is considered by Degkwitz as the optimum time. Grave serum sickness developed in one third of his cases. The failure was thus complete.

Extrapleural Thoracoplasty.—Ziegler had no death in eighty-six thoracoplastic operations in uncomplicated cases. Four of seventeen patients with empyema died. He uses only local anesthesia.

Treatment of Fractures.—Matti deals with some of the present problems in surgery of fractures. He warns emphatically against mobilization and exact reposition of impacted fractures of the neck of the femur in the elderly. He rates the danger from direct extension of the bone higher than that from open reconstruction of the bone. Many mishaps of osteosynthesis methods are due to the use of catgut instead of silk.

Nil Nocere and the Tunica Vaginalis as Test Object.—Lanz tests first the fluids to be injected into the cerebrospinal canal, as well as into the ureters, on the tunica vaginalis propria in patients with hydrocele. Some of the local anesthetics gave no reaction. Colloidal silver caused, in one instance, a grave necrosis and inflammation of the tunica. He prohibited its use in pyelography, and the sad experience since of other clinicians showed that he was right. Sodium bromide (25 per cent) is less irritating than 12.5 per cent sodium iodide.

Multilocular Cysts of the Kidney.—Rovsing cured three patients with polycystic kidneys by multiple punctures of the cysts. No fistulas formed. This might have been expected since the cysts contain no urea.

Contracture of the Hip.—Stanischeff corrects the shortening of the femur in contractures of the hip joint by a pertrochanter osteotomy, cutting the femur through both trochanters and sliding the lower cut surface on the upper to lengthen the femur, concluding with extension by a wire passed through the bone. No plaster. Six illustrations show the technic.

Treatment of Syphilis in Infants. E. Pese.—p. 62.
*Etiology of Scarlet Fever. H. Deicher.—p. 74.

Splenomegaly with Lipoid Cells.—Schiff reports the *first* case of splenohepatomegaly of the Niemann-Pick type diagnosed in the living. The patient was an infant, aged 17 months, and the parents had noticed enlargement of the abdomen from the age of 3 months. The blood picture was about normal, but the serum was pseudochylous. The complexion was pale brownish The enlargement of the liver was more pronounced than in Gaucher's splenomegaly. Puncture of the spleen revealed typical large cells containing fat and lipoids, as described by L. Pick. This decided the diagnosis.

Formation of Casts.—Feuchtwanger and Lederer regard acidosis as the most important factor in the formation of urinary casts in infants Acidosis also increases the amount of urinary colloids, which furnish the material for the casts. They were able to induce albuminuria and cylindruria by administering calcium chloride.

Experimental Rickets.—Gyorgy, Jenke and Popoviciu found that nonirradiated cholesterol and its derivatives have no antirachitic properties Irradiated cholesterol and its ester are active Cholestanols and choleic acid are hydrated products and cannot be activated by irradiation They suggest the possibility of oxidation by the action of light at the point of double binding

Hemoglobin Resistance.—Bischoff and Schulte conclude from the curves of destruction of hemoglobin that infants have two hemoglobins one from the fetal life, which is more resistant, and another, which is formed after birth.

Etiology of Scarlet Fever.—Deicher confirms completely the American work on the etiology of scarlet fever. Not every streptococcus obtained from scarlet fever produces a good toxin He believes that it may be possible to identify these strains better by agglutination tests Streptococci from other sources and some of the streptococci from scarlet fever patients produce other toxins, which are not specific. While a convalescent from scarlet fever has a negative Dick test as a rule, he will react to these nonspecific toxins. A convalescent child with a positive Dick test again became ill shortly afterward with scarlet fever He rates the reliability of a negative Dick test at 98 per cent The failures are partly due to changes in the susceptibility in the same individual.

Change of Sex P Hertwig —p 663
*Gas Metabolism H W Knipping —p 677.

Lipoid Theory of Anesthesia.—Winterstein surveys the evidence against the lipoid theory of anesthesia It is impossible to judge from the solubility in oil as to the solubility in the lipoids of organs The cause of the—not very close—parallelism between the narcotic power and the coefficient of distribution between oil and water is simply the fact that a less water-soluble substance will adhere better to the water-insoluble surface of the cell. Warburg's experiments with shaking of aqueous solutions of narcotics with charcoal gave similar results as shaking with oil. Yet nobody would base on that a "charcoal theory" of anesthesia

Niche in Cancer.—If the niche is larger than a cherry stone, Presser regards cancer as probable.

Pain Conduction in Vessel Nerves.—Hirsch found spinal sensory fibers in the arteries of the extremities.

Heart Hormone.—Haberlandt was able to extract from the heart an alcohol-soluble substance that induced contractions in the frog heart which had been standing still It also accelerated and increased the pulsation

Lipoid Antibodies.—Brandt, Guth and Muller injected rabbits with mixtures of hog serum with lipoids from various sources They found indications of organ specificity, especially with lipoids extracted from brain tissue.

Gas Metabolism.—Knipping fears that the determination of gas metabolism may take the same development in Germany as it did in the United States. He tries to convince practitioners that it rarely pays to acquire such an apparatus and to learn how to handle it. He sees another danger in the production of too simple types of apparatus, as he attributes to America Against this danger he had devised an apparatus which is practically identical with the simplest registering types used commonly in the United States.

Pharmacology of the Kidneys E. Hesse —p 588

Vagus or Carotid Pressure Experiment?—Ortner observed an almost immediate bradycardia (after two to four pulses) on compression of one or both femoral arteries in arteriosclerosis

Virus of Encephalitis and Herpes.—Pette finds no definite reasons for assuming the identity of the virus of epidemic encephalitis and of febrile herpes.

Psychology of Angioneurotic Edema.—Schultz' patient was a man dissatisfied with his wife but faithful to her. He had the habit of taking off each night the wedding ring he wore. On the morning after the departure of his wife for a three weeks' absence, he developed an angioneurotic edema of the ring finger, which made it impossible to replace the ring. The edema disappeared when the wife returned.

Models of Enzymes.—Haehn publishes two models of enzymes. One of them is a combination of chlorides of potassium, sodium and calcium with alanin, l leucin and eventually a peptone It has the action of an amylase The other is a mixture of phosphates with a p_H of 7.1 with addition of glycocoll It oxidizes acetaldehyd and propionaldehyd in the presence of methylene blue, thus resembling Schardinger's milk enzyme (an oxido-reductase).

Roentgenotherapy in Trigeminal Neuralgia.—Walter and Lax are astonished that the roentgen rays are so rarely used in treatment of neuralgia of the trifacial nerve They report nineteen cured by it among twenty-nine cases, six considerably and two distinctly improved The first exposure frequently causes an exacerbation of the pains The technic seems to play a great part in the success.

The Kielland Forceps.—Frey recommends the Kielland forceps for practitioners, but adheres strictly to the old indications in its use.

Raw Sauerkraut in Medicine.—Hartmann extols the advantages of raw sauerkraut. It has a high vitamin content, influences the intestinal flora, and is a household remedy in ascaridiasis.

Hypoglycemia After Denervation of the Pancreatic Artery.—Doppler and Steinmetzer applied an 8 per cent aqueous solution of phenol to the arteries of the pancreas in dogs and rabbits. The blood sugar began to decline in about seventeen days, and reached its minimum (17 to 52 per cent below normal) after twenty-five to forty-seven days more. Then it rose again and eventually declined—probably because of the interaction of the suprarenals.

Pharmacology of Caffeine.—Grossmann and Lušicky found no clinical influence from the double salts of caffeine on the circulation nor on the central nervous system. A real action could be obtained only with pure caffeine or with black coffee.

Action of Heat on Infants.—Demuth, Edelstein and Putzig kept six infants for three or four weeks in a warm room (84-89 F.). An acidotic shifting of the metabolism was the most striking change produced.

Signs of Birth Injury of Brain.—Dollinger attributes various motor irritation phenomena in infants (nystagmus, contractions of facial muscles) to cerebral injury suffered at birth.

Blood Chemistry of Scurvy.—Edelstein and Schmal found practically no changes in the dextrose and calcium concentration of the blood in guinea-pigs with experimental scurvy. The phosphates were lower in some of them, normal in others.

Treatment of Epilepsy.—Freudenberg's patient had no seizures when the sodium chloride concentration of his blood serum was below 0.5 per cent. He used a diet poor in salt and daily administration of 9 Gm. of sodium bicarbonate plus 1 Gm. of potassium bicarbonate to keep the blood chloride low.

Toxic or Dynamic Protein Fever?—Reiche found that even large amounts of proteins do not induce fever in infants, if administered with breast milk. He concludes that protein fever is of toxic, rather than of dynamic origin. It may be due to decomposition products, which can be neutralized by human milk.

Leukocytes in Infants.—Schmal, Schmidt and Serebrijski publish a detailed study on the leukocytes in normal and sick infants and children.

Environment and Growth of Rats.—Vollmer found that inhibition of movements, small cages and dirt slow down the growth of young rats. Daylight or darkness had no influence, but sensitization with eosin before exposure to light promoted the growth.

Metabolism in Pylorospasm.—Vollmer and Serebrijski investigated the metabolism in infants with pylorospasm. They found no signs of hyperirritability of the nerves, and they propound the question, why these patients have no spasmophilia. Another problem is that of a possible vicious circle: The vomiting entails alkalosis; the latter causes vagotonia, and this in turn may increase the irritability of the pylorus. The ammonia excretion was low—and absent in the two gravest cases. The ratio of basic (secondary) phosphates to the acid phosphates was always greater than that of the blood (¼). This alkalinuria persists even after the vomiting has ceased. Only large doses of hydrochloric acid are able to correct this alkalinuria, and this not always. Hypercapnia—up to 114 volume per cent carbon dioxide—was constant. The hydrogen ion concentration of the blood was low in every grave case (p_H up to 7.51). The blood chlorides were low and the urine chlorides still lower. The calcium, potassium and phosphates of the blood were about normal. The hypoglycemia was probably due to alkalosis. They tested with dimethylamidoazobenzene how much hydrochloric acid could be added to the milk. Addition of 4 per cent of normal hydrochloric acid to breast milk, or 6 per cent, if some proteins are added, changes the color of the indicator. The taste of such milk is agreeably acid. It is quite helpful, although it does not restore normal conditions at once. They believe that the low blood chlorine, together with the low residual nitrogen account for the absence of symptoms of tetany in these infants. Many other problems are still waiting for solution; for instance, the peculiar predisposition of boys for pylorospasm.

Treatment of Cancer. H. Auler.—p. 153.
Origin of Cancer. E. Kliment.—p. 157.

Neutral Red Serologic Test for Cancer.—Roffo's test has been described in these columns recently. It is made with 5 drops of a 0.01 per cent solution of neutral red added to 2 cc. of clear serum. Normal serum turns it a yellowish tint. He calls attention anew to the simplicity of the test, the constantly negative findings in nonmalignant disease, and the 100 per cent positive responses with internal cancer.

Biochemical Reactions with Cancer.—Boyksen reports experimental and clinical inoculations with cancer autolysates, and experiences with the serum from animals thus treated.

*The Neuroglia in General Paralysis. S. R. Cajal.—p. 738.

Periodic Paralysis.—Shinosaki has encountered in Japan twenty-four cases of periodic paralysis of the extremities; in 62 per cent there was goiter, including 29 per cent of the exophthalmic type. He found that by giving the patients thyroid or parathyroid preparations he was able to bring on a paroxysm of the paralysis. An epinephrine injection in fifteen cases elicited the paroxysm of paralysis in 15 per cent; in one in this group, besides the paralysis, ventricular extrasystoles appeared, the same as in the spontaneous attacks. In only one case was there glycosuria during the intervals, but three other cases had glycosuria during the paroxysms of paralysis, and 73 per cent of the total had albuminuria during the attacks. In a number of the patients the oculocardiac reflex was pronounced. A family or hereditary tendency is not so constant as others have assumed. Charcot's "Basedow paraplegia" was probably a periodic paralysis occurring in exophthalmic goiter. The necropsy findings in the one case examined were of the exophthalmic goiter type, with hypertrophy of the parathyroids. All the data testify to a polyglandular affection, the thyroid predominantly involved. The clinical picture is exactly the reverse of tetany, and the attacks are liable to be brought on by repose, and by overintake of carbohydrates; the latter may exaggerate parathyroid functioning. The first attack was noted at the age of 54 in one patient, but the majority were in the twenties; none was under 16.

The Necropsy Findings in General Paralysis.—Cajal discusses the technic for silver impregnation of pathologic nerve tissue, and the interpretation of the findings in the brain in general paralysis. He confirms the quantitative increase of the macroglia, and the transformation of the protoplasmic glia of the gray substance into fibrous glia. Areas are found in both the cerebrum and cerebellum in which the vascular lesions are pronounced while the nerve cells and fibers show little change, while in other areas exactly the reverse prevails.

*The Hemolytic Scarlet Fever Streptococcus. N. Kniazeff and L. Alexandrova-Portniagina.—p. 10.
Occupational Injury from Dust. F. Prinzing.—p. 115.

Hemolytic Properties of Scarlet Fever Streptococci.—Kniazeff and Alexandrova-Portniagina found hemolytic streptococci in the throat of about 50 per cent of scarlet fever patients; in the cerebrospinal fluid and blood of 3 per cent of patients with a grave form of scarlet fever, and always in the blood of cadavers. At the onset of the disease the hemolytic streptococci were much more frequent in the severe form than in the mild, or in convalescents. Hemolytic streptococci were detected in about 7 per cent of healthy children (from 18 months to 14 years old), in none of eight cases of other infectious diseases, and in 10 per cent of persons in contact with scarlet fever patients. Within the first days of the disease, all the streptococcus colonies displayed a hemolytic property, but lost it gradually. The hemolytic power of the streptococci disappeared completely by the fourth week of the disease. On the other hand, the number of nonhemolytic strains increased correspondingly. In artificial nutrient mediums, the streptococcus seemed to conserve its vitality and hemolytic potency for four months. The associated microbes did not seem to influence the hemolytic property of the scarlet fever streptococcus. Changes of hemolysis were noted in bouillon cultures of the streptococci after blood from scarlet fever patients had been added.

Acidosis. G. Becker.—p. 313.
Blood in Chronic Endocarditis. O. Ottander.—p. 336.
Hallucinations in Hemianopia. A. Grönberg.—p. 355.
*Nitrites in the Urine. E. B. Salén.—p. 369.

Air Embolism in Pneumothorax.—Lindblom's patient died from air embolism a few seconds after the introduction of a closed needle. The instrument had pierced a small vein, and the air had been driven into it by a cough.

Nitrites in the Urine.—Salén confirms the occurrence of nitrites in the fresh urine in the presence of certain germs, especially the colon bacillus, in the urinary tract. Yet he doubts the value of the test except for preliminary orientation. The nitrites may cause a positive guaiac test even without addition of peroxide.

*Ovarian Endometriosis. C. Semb.—p. 257.
*Alkali Treatment for Nonhealing Fractures. E. Platou.—p. 287.
Extract of Lung Tissue in Therapeutics. Mentz von Krogh.—p. 294.
*Fracture of Cervical Vertebra. K. Haugseth.—p. 298.
Dietetic Treatment of Diabetes. H. C. Geelmuyden.—p. 300.

Heterotopic Endometrial Implants.—Semb comments on the great variety of organs in which this endometriosis develops. The adenomyomas containing tissue resembling uterine mucosa do not fit into any known class of tumors. They represent actual endometrium outside of the uterus, and behave as such. He found them in 5.5 per cent of 126 ovarian tumors, corresponding to 10 per cent of the benign cystic tumors of the ovary examined. In six other cases, they were found on the intestine, exterior of the uterus, ligaments or tubes. He tabulates the findings in the seven ovarian cases. Extensive formation of bands and adhesion to the peritoneum was constant, evidently secondary, testifying with other findings to an exceptionally irritating action from the contents of these cysts, all of the tar-cyst type. No other cause for the adhesions could be detected. In one virgin, they filled the entire small pelvis. The clinical picture in all was that of chronic pelvic peritonitis. Only two of the women were married. Nothing indicated malignancy in these cases.

Alkali Treatment of Pseudarthrosis.—Scarcely a trace of callus formation was evident even by the sixth month after the fracture, although the conditions had been ideal for consolidation. Platou then gave the man sodium bicarbonate as if he had diabetes. In two months, consolidation was complete. This treatment was suggested by Frølich's success in the opposite line, curing a boy with a grave case of ossifying myositis by inducing acidosis. It is a common experience that fractures do not heal well in diabetics with acidosis.

Fracture and Dislocation of Cervical Vertebra.—In Haugseth's case, laminectomy cured the grave spastic paralysis after fracture of the fifth vertebra with dislocation of the fourth.

Metal Salts in Therapeutics. L. E. Walbum.—p. 298. C'cn.
Extraction of Teeth in General Anesthesia. M. Melchior.—p. 303.

Diastase in the Urine.—Fabricius-Møller found unusual amounts of diastase in the urine in twenty-three cases of tenderness in the region of the pancreas. In eight of the cases, disease of the pancreas was confirmed by operation or necropsy. In seven there was mild pancreatitis or merely compression from a gallstone, and the diastase and the tenderness disappeared after the jaundice had subsided or the gallstone been passed in the stools, or both. The diastase content ranged from 250 to 16,000 units in this group. In three other cases the diastase content ranged from 200 to 1,000 after subsidence of a mild pancreatitis under medical measures alone. In another case of 500 diastase units, there was a juxtapyloric ulcer; in another with 250 there was jaundice from gallstones or cancer metastasis, and in one with 300, cholecystitis was beyond question. In this last group of eight cases, pancreas disease was not certain but it was equally difficult to affirm that the pancreas was sound. Clure and Pratt regard up to 500 as the physiologic range, while others accept 120-150 as the upper limit. In twenty-four cases of gallstone jaundice with no signs of injury of the pancreas, the diastase was within the normal range. In only three of 200 persons with surgical affections not involving the pancreas was the diastase between 120 and 150; all the others were below this figure. He has simplified the usual test for diastase and emphasizes the instructive response in acute abdominal affections. The findings may be misleading after ether anesthesia.

USE OF INJECTED IODIZED OIL IN ROENTGEN-RAY DIAGNOSIS

OF LARYNGEAL, TRACHEAL AND BRONCHOPULMONARY CONDITIONS *

SAMUEL IGLAUER, M.D.
CINCINNATI

The introduction of a contrast substance into the bronchial tree as an aid to roentgenographic diagnosis was first practiced by Jackson.[1] For the purpose of lung mapping he employed dry bismuth subcarbonate, which was insufflated through a bronchoscope.

In 1918, Stewart and the late Dr. Lynah[2] demonstrated excellent roentgenograms of pulmonary abscesses and bronchiectatic cavities which had been filled with an emulsion of bismuth in olive oil.

The endobronchial injection of lipiodol, an iodized vegetable oil containing 40 per cent of iodine by weight, was first practiced by Sicard and Forestier[3] after they had successfully employed it in the spinal canal and other body cavities. The oil and iodine are firmly bound and, owing to its marked radiopacity and nonirritating qualities, lipiodol has proved to be an excellent medium for bronchography.

Forestier and Leroux,[4] Sergent and Cottenot[5] and others repeated the experiments with gratifying results. It was soon discovered that, since the oil gravitated into the most dependent portion of the lung, the course of its flow could be directed by changing the position of the patient.

Delille,[6] who confined his work to children, detected a series of cases of bronchiectasis in patients who had been confined in a sanatorium under the mistaken diagnosis of tuberculosis.

The French school, in general, employs two methods of introducing the oil. The first consists in anesthetizing the larynx (and trachea) and then injecting lipiodol with a laryngeal syringe, provided with a long cannula, introduced above or below the glottis. In the second method a small curved trocar and cannula is thrust through the cricothyroid membrane into the trachea, and a diluted procaine solution is then injected through the cannula to check the cough reflex, after which the iodized oil is also introduced through the cannula

In 1925, Clerf,[7] as well as Ballon,[8] injected the oil through a long cannula inserted through a bronchoscope.

Recently, Beck and Sgalitzer[9] of Vienna employed a retention catheter introduced through the larynx, and directed the flow of the oil by placing the patient before the fluoroscope while the oil was being injected.

Haslinger[10] employs a specially devised bronchus tube, which is guided into the bronchus under fluoroscopic control.

Nather[11] describes an original method. After cocainization of the larynx and hypopharynx, the patient is instructed to swallow the oil. According to Nather, in a majority of instances the fluid will be swallowed the wrong way; i. e., into the trachea.

The German preparation of iodized oil is marketed under the name of "iodipin" (40 per cent), while the Danish product is designated "iodumbrin"[12] and is said to be more opaque than lipiodol. I have used both iodipin and lipiodol and can note no marked difference either in their local action or in their opacity. In order to avoid any possible chance of iodism, Dyroff[13] has just reported the use of a new preparation, "contrastol," in which bromine has been substituted for the iodine radical. Unlike iodized oils, "contrastol" is readily sterilized by boiling.

VARIOUS INJECTION METHODS

The introduction of iodized oil is a laryngologic problem. The use of the laryngeal syringe requires

considerable training and is rather difficult if the patient's body is inclined at an angle in order to inject some particular region of the lung.

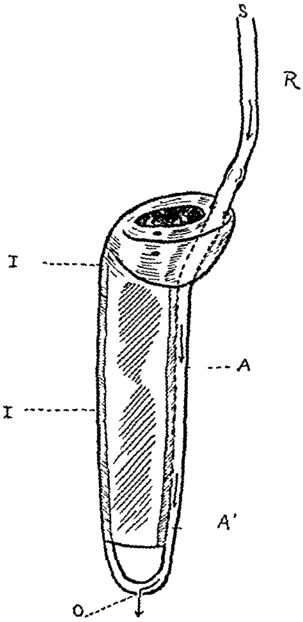

Fig 1.—Double barreled intubation cannula, with large channel for breathing and smaller channel for injecting oil *I I'*, air channel; *A A'* oil cannula, *O*, outlet for oil cannula, *R*, rubber tubing, *S*, syringe attachment, arrows indicate direction of oil flow

Puncture through the cricothyroid membrane gives a direct approach, but the trachea may be missed and the oil may be injected into the peritracheal tissues. I have witnessed two cases in which this accident occurred in expert hands. The occurrence of interstitial emphysema and slight hemorrhage has also been reported.

The bronchosopic method is undoubtedly the most certain and offers the additional advantage of permitting direct inspection and removal of specimens. The bronchoscope, however, cannot be generally employed because the patient may object to its use and because of the special training required for its manipulation.

The catheter method is simple and permits of easy injection under fluoroscopic control. However, it requires considerable cooperation on the part of the patient, who must hold the catheter fixed between his teeth. Its use is obviously not very practicable in children.

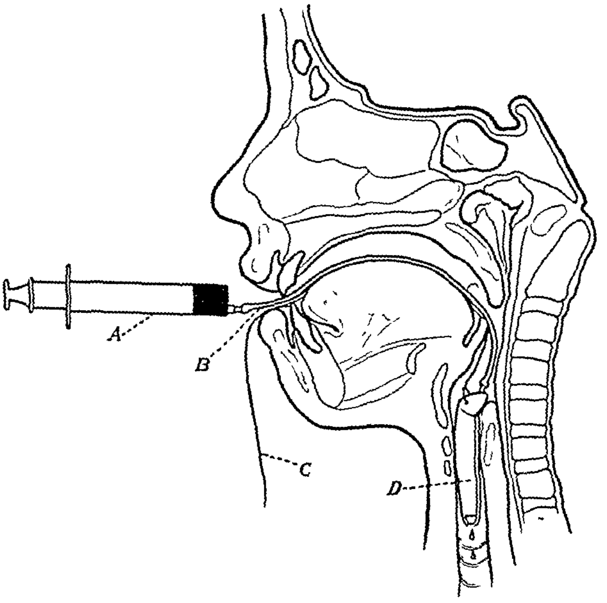

Fig 2.—Intubation cannula in situ: *A*, syringe containing oil, *B*, rubber tubing; *C*, extracting string, *D*, intubation cannula.

The swallowing method is uncertain and involves the problem of oral sepsis.

My own work has been carried on chiefly with the bronchoscope and with the use of a special intubation tube which I have devised for this purpose.

Intubation Method.—Intubation Cannula: The instrument consists of a shortened metal O'Dwyer tube with a longitudinal groove cut in the back wall into which a small bore secondary cannula is soldered. The accessory cannula (designed to convey the oil) is somewhat longer than the O'Dwyer tube and terminates above in a nipple, over which a long piece of rubber tubing is slipped. Below, the secondary cannula extends in a semicircular prolongation beyond the O'Dwyer tube, to insure the entrance of the oil into the trachea (fig. 1). The semicircular extension facilitates the introduction of the intubation cannula. When inserted into the larynx, the double barreled arrangement provides one channel for the injection of the oil while the main channel remains unobstructed for breathing purposes.

Technic: In order to obtund the cough reflex, a preliminary dose of codeine or morphine is administered. In the adult, the larynx is anesthetized with a 10 to 20 per cent solution of cocaine. In young children, this is omitted. A long piece of rubber tubing is attached to the oil cannula, and the intubation tube is threaded in the usual manner for safety and extraction. The intubation tube, carried on an obturator, is then introduced into the larynx under the guidance of the laryngoscopic mirror. In young children it is inserted by touch. Through the rubber tube which projects from the patient's mouth, a small quantity of cocaine solution (2 per cent) or procaine (3 per cent) is injected into the trachea to abolish the cough reflex.

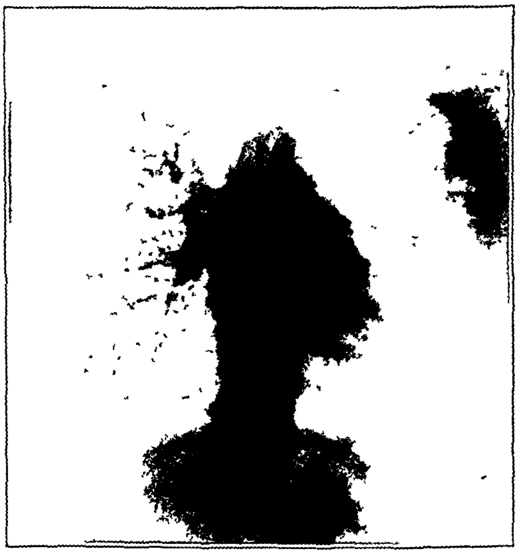

Fig. 3.—Pulmonary tuberculosis involving the right lung: Trachea slightly deflected to the right; lung injected with the patient lying on the right side, the right tracheobronchial tree is filled with the exception of the infiltrated apex, which the oil could not penetrate.

In the roentgen-ray room, a glass syringe containing warm iodized oil is attached to the rubber tube through which the oil is slowly injected into the trachea (fig. 2). Should the patient cough, the intubation tube acts as a baffle and tends to prevent the escape of the oil into the pharynx. By varying the position of the patient, one causes the oil to gravitate into any desired portion of the lung. If the patient is placed on his side, the dependent lung may be injected throughout (fig. 3). It is often advantageous to control the direction of flow by placing the patient before the fluoroscope while the oil is being injected. Since the oil may diffuse rapidly or be expectorated with the return of the cough reflex, the roentgenogram should be taken immediately after the injection. From 15 to 20 cc. will usually suffice for visualizing one lung. As much as 40 cc. of oil may be introduced. Both bases or one lung may be filled at one time, but it is not advisable to fill entirely both lungs at one sitting.

The intubation tube is withdrawn by traction either before or after the picture is taken.

Advantages: The advantages of the intubation method lie in its comparative simplicity and its applicability to all ages. Little cooperation is necessary on the part of the patient, who is free to move about and can be comfortably placed in any desired position. Fluoroscopic control of the injection may be readily employed, while the baffle action of the tube tends to prevent the escape of the oil from the trachea.

ROENTGENOGRAPHY

The roentgenography in connection with this paper was carried out by Drs. George Benzing and Samuel Brown. The films were taken in either the upright or the recumbent posture. The best films were obtained when the patient held his breath at the end of a deep inspiration. Stereoscopic films were made whenever possible, and lateral views were also found to be of value.

Normal.—The normal tracheobronchial tree is beautifully delineated after injection. The trachea in the midline of the body stands out clearly, and occasionally the outlines of individual rings are clearly visible. The carina and main bronchi are readily located, and the tapering arborescent structure of the bronchi give a very striking picture. The alveoli are frequently filled as far as the peripheral pleura (fig. 4).

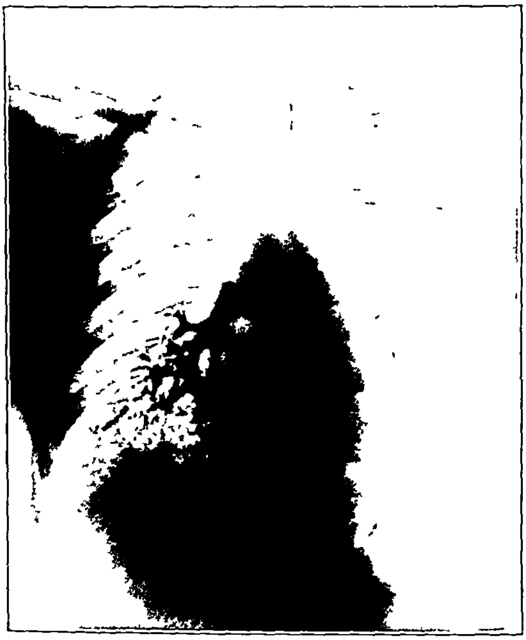

Fig 4.—Normal tracheobronchial tree injected with iodipin, 18 cc, introduced through intubation cannula: The trachea, main bronchi, the bronchioles and some of the alveoli in the lower lobes are well delineated.

Pathologic.—Larynx: In the literature, no reference is made to roentgenography of the larynx visualized by injection. For the purpose of studying the lumen in the stenotic larynx, the oil was injected into the larynx and a profile picture was snapped while the oil was flowing through the larynx. In several cases the narrowed subglottic region was well delineated.

In tracheotomized patients, the following procedure was adopted: A finger cot was filled with a fluid contrast substance, and a string was tied to each end of the finger cot. A probe, carrying a long string, was passed through the tracheal fistula into the pharynx and out of the mouth The oral end of this string was then attached to one end of the finger cot, the tracheal cannula was reinserted, and the finger cot was pulled into the larynx By this method the dimensions of the narrowed subglottic lumen of the larynx could readily be demonstrated in the roentgenogram (fig. 5).

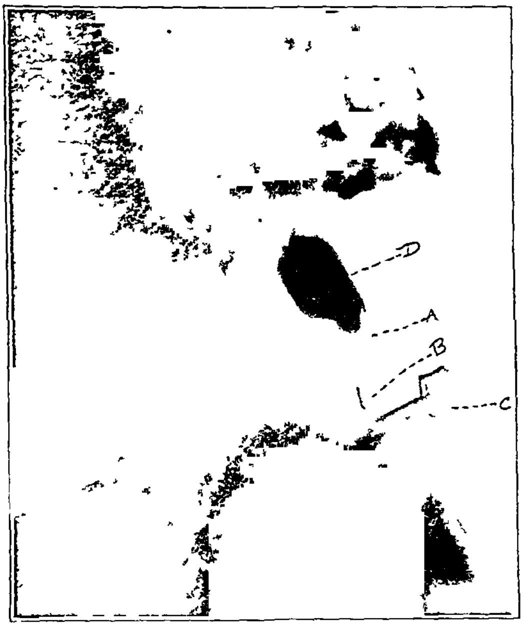

Fig 5.—Tracheotomized patient: Finger cot filled with opaque material has been pulled into the larynx from above; the stenotic area extends from *A* to *B* above the cannula, *C*, distended portion of finger cot, *D*, is in the hypopharynx

Trachea and Bronchi: Distortion, obstruction or displacement of the trachea and main bronchi are delineated with much greater clearness than in ordinary roentgenograms. Occasionally a reservoir bronchus pulled up by fibrosis or adhesions may be demonstrated.

Bronchiectasis: The diagnosis of bronchiectatic cavities, which hitherto has been very difficult for both internists and roentgenologists, is greatly simplified in the injected lung. The bronchiectases stand out as club-shaped, grapelike, or fusiform swellings, along the course of the bronchial tree (figs. 6 and 7).

The following case is rather illuminating:

In 1926, an ex-soldier, claiming disability as a result of his service during the World War, was admitted to Diagnostic Center no. 1 in the Cincinnati General Hospital. His chief complaints were cough and profuse expectoration. He had been refused compensation at four Veterans' Bureau examination centers on the ground that his illness had no service connection. Bronchography after injection disclosed two large bronchiectatic cavities situated behind the heart shadow. The disease was then retraced to an attack of influenza contracted in March, 1919, and the patient was awarded back compensation from that date forward.

Lung Abscess: It is not always possible to inject a lung abscess. This may be due to the fact that the cavity is filled with secretion or has a very narrow connection with a bronchus. If the cavity can be evacuated through a bronchoscope, the oil may then be injected. The relation of the cavity to the bronchial tree should in a large measure determine whether the case should be treated by bronchoscopy and irrigation or by surgical measures. It is apparent that a peripherally located abscess with a narrow drainage bronchus is unfavorable for endobronchial treatment.

Tuberculosis: Although some authors, fearing congestion and hemorrhage, have expressed some doubt as to the advisability of injecting tuberculous lungs, Archibald[14] and Ballon[8] undertook bronchography in a large series of such cases without noting any bad effects.

Cavities: The study of cavitation is interesting. Some difficulty may be encountered in filling apical cavities; but, on the other hand, unsuspected cavities may be disclosed. In one of our patients who had been under close clinical and roentgen-ray observation for three years, a large basal cavity with poorly defined walls was delineated for the first time after iodipin had been introduced (fig. 8).

Pneumonography.—Pneumonography gives valuable information as to the limits and thickness of the cavity walls. A poorly defined wall indicating softening makes the prognosis more unfavorable. The differential diagnosis between an infiltrated lung area and a thickened pleura or effusion may be determined by pneumonography. After artificial pneumothorax, interesting observations have been made by Geriaud and DeRegnier,[15] showing that some function still remains despite the collapsed condition of the lung.

One of our cases of pneumothorax showed that the bronchial structures as a whole were firmly compressed against the larger bronchi.

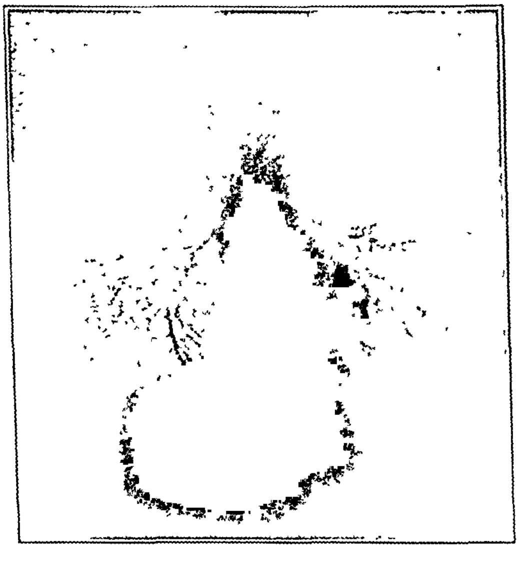

Fig. 6.—Numerous fusiform bronchiectatic cavities in the left lower lobe. Patient was injected with about 9 cc. of lipiodol in each lung.

Archibald[14] finds bronchography valuable in establishing the indications for thoracoplasty, and also employs it in the study of the progress of cases after operation.

Fistula: Moeller and von Magnus[12] injected the outlet of an empyema fistula and found that the iodumbrin had entered a bronchus, thus demonstrating the presence of a bronchopneumopleural fistula. The fistula, which had shown very little tendency to heal, closed within three weeks after the treatment.

Tumor: Injection of the lung aids in the differential diagnosis between tumor and abscess. In tumors of the pleura or lung parenchyma, the injected bronchi either terminate at the site of the tumor or seem to be pushed aside by the growing neoplasm. The value of bronchography in this condition is greatly enhanced if it is combined with bronchoscopy.

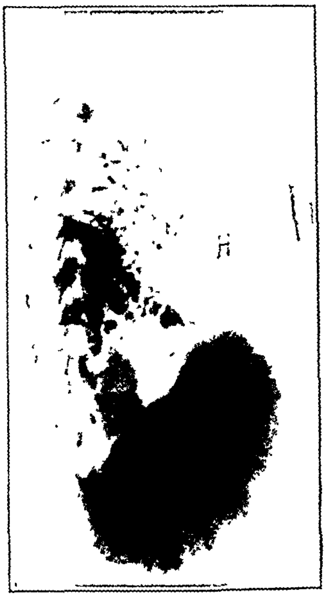

Fig. 7.—Lateral view of chest showing numerous grapelike bronchiectatic cavities in the base of the left lung behind the heart shadow, *H*. Patient was injected with about 18 cc. of lipiodol.

EFFECTS OF INJECTING THE BRONCHI

As a rule, endobronchial injection is well borne by the patients, and no disturbing after-effects are encountered.

Dyspnea. — Dyspnea during and shortly after the injection occurred in a few of our cases, and was especially marked and persistent in one patient with a collapsed lung, the oil entering the functioning lung. Severe dyspnea and cyanosis were observed in a patient with myocardial insufficiency. Ordinarily, when dyspnea occurs it is probably due to the mechanical effect of the oil combined with susceptibility to cocaine. Slow injection tends to diminish the mechanical factor.

Fever.—A slight febrile reaction frequently follows the introduction of the oil. The fever usually subsides within a day or two. In exceptional cases, it may persist for several days. Expectoration is usually increased for a few days after the introduction of the oil, after which the quantity of sputum may become normal or even subnormal.

In one of our cases of pulmonary tuberculosis, the patient expectorated some blood for the first time a few days after the injection. In two other cases which had been under clinical observation for some months, tubercle bacilli appeared for the first time after the oil had been introduced, thus establishing the diagnosis, which had been uncertain in both patients. This test may prove of value in doubtful cases, and is comparable to the diagnostic expedient with potassium iodide administered for the purpose of freeing tubercle bacilli in the sputum. Injection of the oil is contraindicated in febrile or cachectic patients and in those with cardiac decompensation.

Elimination.—A considerable portion of the injected oil is ejected by expectoration. The remainder is eliminated by absorption. According to Moeller and von Magnus, no traces of iodine could be found in the urine after a lapse of six days. In two of our cases, bronchography showed remains of the iodipin in the lung five weeks after it had been injected.

SUMMARY

1. Injected iodized oil has proved to be an excellent contrast substance in roentgenography of the larynx, trachea and bronchi.
2. The oil may be introduced by several methods, including injection with the laryngeal syringe, puncture through the cricothyroid membrane, injection through a bronchoscope, insertion of a catheter into the trachea, or the "swallowing" method.
3. The insertion of a specially devised double barreled intubation tube, with a main channel for breathing and a secondary channel for the oil, provides a simple and effective method for endotracheal injection. It may be used in both children and adults (figs. 1 and 2).
4. In order to direct the flow of the oil into a particular area or region of the lung, it is frequently advantageous to inject the bronchi and change the position of the patient, under fluoroscopic control.
5. The normal tracheobronchial tree is beautifully delineated after injection.
6. In the stenotic larynx, the extent of the obstruction may be visualized by the introduction of radiopaque substances.
7. Distortion and displacement of the trachea and bronchi are clearly delineated.
8. Bronchiectasis, lung abscess, cavitation, the limit of pulmonary tumors and bronchopulmonary fistulas are plainly outlined.
9. As a rule, endobronchial injection of oil is well tolerated by the patients. Occasionally, dyspnea and some fever ensue.
10. Injection is contraindicated in febrile or cachectic patients and in those with cardiac decompensation.

ABSTRACT OF DISCUSSION

Dr. I. D. Bronfin, Sanatorium, Colo.: As internists, especially those of us who are called on to treat diseases of the lungs, we are greatly interested in this method of diagnosis. I myself have had comparatively little experience with this method, but it opens up a new and valuable method of diagnosis of certain diseases of the lungs which heretofore have caused great perplexity to internists. With regard to the method of injecting the oil, we who practice in tuberculosis sanatoriums are obliged to acquire a certain amount of skill in the use of the laryngoscope. We have not found any especial difficulty in training patients for the ordinary intratracheal method. The question is often raised as to how much injury is caused by the oil. I have not found any. The oil does not seem to cause any irritating effect on the pulmonary tissues as far as can be detected by auscultation. I used it first in a case of bronchiectasis in which the roentgen ray did not bear out the diagnosis. The iodized oil is still present in the lung, after sixteen weeks, but no râles are present. That opens up the question of the extent of injury a foreign substance causes to lung tissue. A few years ago such a study was made by Corper in which he showed that the presence of oil produced some infiltration of the pulmonary tissue. Clinically it has not been borne out, but it seems that there must be a little caution in using this oil. It will require a great deal of experimental work and investigation to determine this point. In cases of bronchiectasis we can usually make a diagnosis by the symptoms; but the presence of an abscess cavity in the lung is sometimes hard to detect, and if this oil will help to diagnose those cases it will prove a valuable method to the internist.

Dr. Thomas E. Carmody, Denver: I have used this oil for about a year and have had a number of roentgenograms made in these cases three or four months afterward, finding a large amount of the iodized oil still in the lung. I have not used it in tuberculous cases, as Dr. Iglauer and Dr. Bronfin have, because I did not wish to pass a bronchoscope in those cases. I have used it almost entirely through the bronchoscope, although sometimes with the tracheal syringe, and I do the same thing Dr. Iglauer does with the intubation tube although not quite so easily; but in a case in which the patient is very ill with lung abscess or any wasting condition and one wishes to map out the lung, I believe that the intubation tube will help a great deal. I had one case in which I mapped out the esophagus as well as the trachea, which is important from the standpoint of stenosis or diverticula. I believe Dr. Iglauer has brought forward something which, together with the discovery of iodized oil, will help us a great deal in mapping out these cavities. The roentgen ray alone will not map out many of them, but the injection will help us to show the cavity. One case that Dr. Iglauer showed did not appear on the roentgenogram before injection; and while the roentgenologist may be very thorough and be able to interpret the plate, the iodized oil will help him and help us.

Dr. Samuel Iglauer, Cincinnati: Dr. Bronfin raised the question of the injury to the lung from the injection of this foreign substance. This oil has been used in France for three years, and in this country for more than a year. It has been used in Denmark and in Russia, and the consensus is that it does no harm, especially to the normal lung. In pulmonary tuberculosis there is a question as to whether it does harm, but naturally the tuberculous patient will react readily to any slight insult. Two patients that were injected had never shown tubercle bacilli until the oil was introduced, and in a few days tubercle bacilli appeared in large numbers. In these cases it was of value from a diagnostic standpoint. Some of the tuberculous patients were ill for a week, especially one man who had had a thorocoplasty. Archibald, before performing a thorocoplasty, injects the tuberculous lung with this oil, and after the operation if the case does not proceed in a normal manner he may reinject to see why there is no improvement. Dr. Bronfin said that the diagnosis of bronchiectasis is usually easy. I am told by internists and roentgenologists that it is always difficult. Dr. Carmody spoke of the retention of the oil in the lung parenchyma. It is true that in pathologic cases it may remain for several weeks, but it seems to have no irritating effect. Another point about using this oil in tuberculosis: If it is true that the iodine has some bad effect on the tuberculous lung, it can be done away with by using the new oil which has just been discovered—a contrast oil which does not contain iodine but bromine, firmly bound. As regards the introduction of lipiodol with a syringe, it is quite possible to inject the

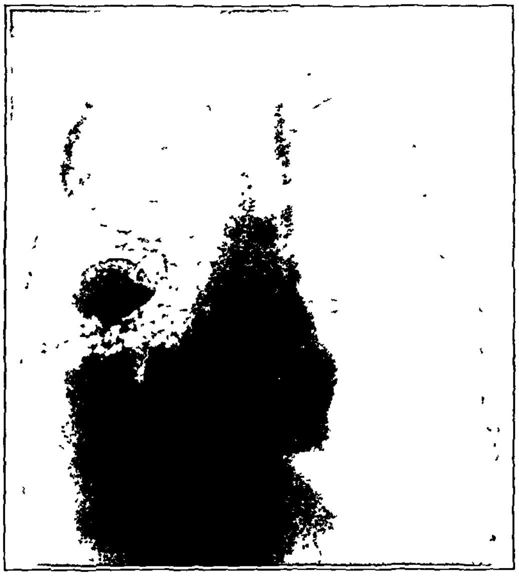

Fig. 8.—Pulmonary tuberculosis: Large cavity in right lower lobe filled with iodipin; the drainage bronchus is delineated; this patient had previously had numerous roentgenograms which had failed to show the presence of a cavity.

trachea by the ordinary injection method; but if, for example, one wishes to put the patient on his right side and inject the oil, one will have to stand on one's head. If the intubation tube is inserted, one can put him in any position and he is comfortable and can breathe through the tube. Furthermore, if he happens to cough, the intubation tube acts as a baffle, and one does not have the oil ejected and swallowed as one would with a syringe. I have had no fatalities. About a week after I had made the injection, a patient died with generalized septicemia with miliary abscesses in the spleen, etc. One of the contraindications is that this oil should not be injected into a very ill patient.

PHYSIOLOGY OF SYMPATHETIC NERVOUS SYSTEM IN RELATION TO CERTAIN SURGICAL PROBLEMS *

ALEXANDER FORBES, M.D.
AND
STANLEY COBB, M.D.
BOSTON

The proposal to relieve spastic paralysis by surgical interruption of the sympathetic innervation of the muscles involved rests on the theory that a special function, designated "plastic tonus," depends on the sympathetic nerve fibers, and that abolition of this plastic tonus will relieve the pathologic condition. The theory seems to have arisen, in the first place, from the anatomic observations of Boeke,[1] which apparently establish the innervation of certain skeletal muscle fibers by sympathetic as well as by cerebrospinal nerve fibers. Subsequent investigations by various workers leave little doubt that in some, at least, of the skeletal muscles there are striated fibers innervated by sympathetic nerve fibers; but whether these fibers exist in all muscles and whether they differ histologically from the muscle fibers innervated by medullated nerve fibers are unsettled questions.

The functional significance of these fibers has been a matter of more speculation than observation. Some observers have reported a loss of tonus in skeletal muscles, following section of their sympathetic innervation.[2] A larger number of observers have failed to substantiate this finding.[3] The more recent development of the subject has involved the alleged distinction between "contractile" and "plastic" tonus. Sherrington[4] first called attention to the remarkable plasticity of the limb of a decerebrate animal. The limb shows a tendency to remain in whatever position is passively imposed on it, the muscle maintaining the requisite tension irrespective of length. Sherrington gave convincing reasons for interpreting these phenomena as the result of proprioceptive reflexes; that is, as reflexes set up by excitation of sensory receptors within the muscle substance and afferent nerve impulses arising therefrom. But Sherrington did not postulate a special neuromuscular mechanism for mediating the plastic effect, distinct from that involved in ordinary contraction of the muscle.

Langelaan[5] sought to establish two separate mechanisms and functions in the muscle: a contractile mechanism and a plastic mechanism. Hunter[6] assumed Langelaan's distinction to be well founded, and endeavored to show that the plastic element in tonus is eliminated by sympathectomy, while the contractile element is not disturbed. On the basis of Hunter's theory and the experiments in support of it, Royle[7] developed the operation of ramisection by which he asserts that he has relieved certain cases of spastic paralysis.

As to the validity of Langelaan's hypothesis of distinct plastic and contractile functions in muscle, it is pure speculation based to a considerable extent on misunderstanding of the work of previous observers.[8] Furthermore, it fails to harmonize with the known facts of nerve-muscle physiology. It is well established that when a nerve or muscle is stimulated, the resulting functional response is of an all-or-none character. It is independent both qualitatively and quantitatively of the strength or nature of the stimulus, provided this is adequate. One cannot vary the character or amount of response in a nerve impulse or the resulting muscle response by changing the character of the external stimulus any more than one can vary the speed of a rifle bullet by varying the pressure with which the trigger is pulled. Since all experiments indicate that nerve fibers and muscle fibers respond in the same manner to all stimuli, artificial or otherwise, it is difficult to see how the nerve fibers could be made to con-

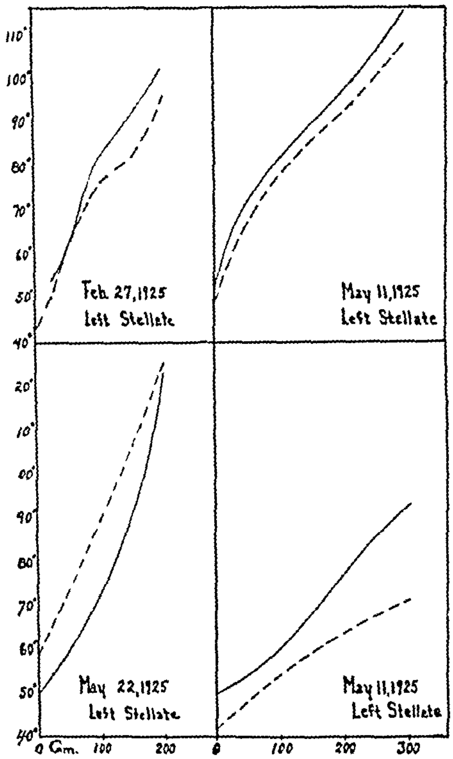

Fig. 1.—Curves correlating elbow flexion with flexing force applied in stellate experiments: Abscissas, tension applied to wrist perpendicular to ulna; ordinates, degrees of flexion; solid line, operated limb; broken line, control. February 27, three days after operation, measurements made one hour after decerebration; May 11, seventy-six days after operation, upper curves twenty minutes, lower curves three hours after decerebration; May 22, seventy-four days after operation, one and one-half hours after decerebration.

duct the alleged plastic influence whereby the length of the muscle is caused to remain unchanged, without any release of contractile effort such as results from ordinary excitation. All the known facts of plastic tonus can be explained in terms of the well known, all-or-none type of response in the individual nerve and muscle fibers, as has been shown by the work of Liddell and Sherrington[9] and of Fulton.[10] A serious objection to the theory of the influence of the sympathetic nerves on muscle tonus is the absence of any contractile response to artificial stimulation of these nerve fibers; and supplementing this is the absence of the effect of drug action that one would expect in tissues innervated by the sympathetic fibers.[11] Finally, there is the preponderance of evidence from previous investigations of sympathectomy, tending to show no consistent change in tonus at all resulting from this procedure. The positive results of Hunter were too few to justify a final conclusion in a problem so beset with possible sources of error.

Although the theory of a plastic function as distinct from contractile function is untenable, it is nevertheless possible that sympathectomy might have some effect, if there are indeed skeletal muscle fibers innervated by sympathetic nerve fibers. If these particular fibers participate in the postural reflex known as decerebrate rigidity, we should expect a slight decrease in rigidity after they are cut. If the contraction of these particular fibers is more sluggish than that of the fibers innervated by the cerebrospinal nerves, we should expect the contraction and relaxation of the muscle as a whole, after their elimination, to be somewhat more brisk. In other words, the muscular contraction would resemble less than ever the slow, plastic type of contraction found in smooth muscle. If this were actually observed, there might be some basis for the assertion that there is a decrease in plasticity following sympathectomy or ramisection.

Hunter maintained that the effects of sympathectomy became more marked for several weeks after the operation was performed. If these effects were due to the mere withdrawal of efferent sympathetic impulses from the muscles there could be no such progressive increase in the effect, for impulses cease to flow from the cut surface of a nerve within a few seconds after the section is made. There might, however, be a delayed effect due to metabolic and physical changes in the muscle.

With these facts in mind, experiments were performed on a series of seventeen cats by Forbes, Cannon, O'Connor, Hopkins and Miller.[12] In eleven of these the fore limb on one side was deprived of its sympathetic innervation by removal of the stellate ganglion; in the other six, the abdominal sympathetic chain of one side was removed. In three of the animals they performed decerebration first, and then, after observing whether or not decerebrate rigidity was symmetrical on the two sides, performed the sympathetic operation and observed the immediate effect of it, if any. In all the rest of the series the sympathetic operation was performed first aseptically, and after a period of from three to eighty days the animal was decerebrated, and rigidity on the two sides quantitatively studied by means of spring balances to measure the tension of muscle, and protractors to measure the angles of the elbow or ankle joints.

These experiments showed, in the first place, that if precautions are taken to avoid confusion due to the influence of asymmetrical posture (shown by Magnus and de Kleijn to modify decerebrate rigidity), tonus will usually be approximately symmetrical on the two sides in a decerebrate animal, prior to sympathectomy, and a fairly satisfactory basis can thus be found for testing the effect of the operation. But uncontrolled changes in decerebrate rigidity occasionally occur and render the basis of comparison unreliable. A large number of consistent results would be needed to warrant conclusions.

As to the effect of sympathectomy, the results of these experiments were by no means uniform. Comparison of the operated limb with its mate usually showed almost perfect symmetry; that is, no appreciable difference. Sometimes there was less rigidity on the operated side, sometimes more. Averaging the measurements of the entire series showed slightly less rigidity on the operated side, but this difference was small compared with the individual fluctuations in both directions making up the average. Typical curves of tonus from these experiments are shown in figures 1 and 2. Figure 3 shows an animal in which the sympathectomized limb consistently showed more rigidity than its mate. The conclusion from these experiments was that, if there was any loss of tonus in consequence of the operation, it was insignificant. Certainly, decerebrate rigidity persisted at least approximately undiminished after sympathectomy, and continued to manifest its plastic features.

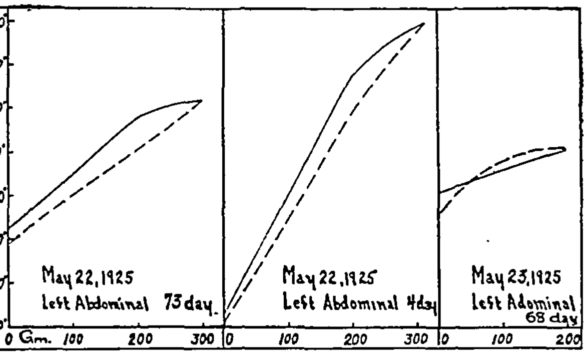

Fig. 2.—Curves correlating ankle flexion with flexing force applied in abdominal sympathetic experiments: Abscissas, tension applied to foot perpendicular to metatarsal bones; ordinates, degrees of flexion; solid line, operated limb; broken line, control. May 22, four days after operation, measurements forty minutes after decerebration. May 22, seventy-three days after operation, measurements fifty minutes after decerebration. May 23, sixty-eight days after operation, measurements one hour after decerebration.

Since the paper describing these experiments went to press, a communication by Kuntz and Kerper[2] has appeared in which a somewhat more refined mechanical method is used for measuring tonus in the knee extensor muscles. A sympathectomized limb was compared with its mate in the otherwise intact animal; that is, the decerebrate preparation was not studied. The results of these authors seem to show a consistent diminution of tonus following sympathectomy, thus confirming Hunter and Royle; but the intact cerebrum complicates the problem of interpreting these experiments. In addition to their experiments on cats and dogs, they repeated Hunter's experiments on birds and corroborated his observations, which point strongly to a postural reflex mechanism involving the sympathetic nerves, more plastic than the corresponding reflex mechanism of the somatic nerves. The experiment seemed to show that whereas the somatic nerves tend to hold the wing in its normal posture but are inadequate to do so without the aid of the sympathetic nerves, the latter tend to make the wing retain whatever posture is imposed on it. The results are highly suggestive, but it is uncertain to what extent the mammalian neuromuscular organization resembles that of birds.

Orbeli [13] reports that stimulation of the sympathetic nerves simultaneous with threshold stimulation of the somatic nerves adds nothing to contraction until fatigue appears. With the onset of fatigue, sympathetic stimulation increases the contraction evoked by somatic stimulation. The sympathetic effect shows a much longer latency than muscular contraction evoked by motor-nerve stimulation, a latency which approximates that of the action of the sympathetic nerves on the heart. These observations suggest that the nerve impulses reaching the muscle fibers by this channel act on them in a different manner from the ordinary somatic motor nerve impulses. Apparently they do not stimulate the muscle; that is, they do not cause contraction. Yet it is conceivable that at the sympathetic nerve endings a chemical effect of some sort is produced which alters the state of the muscle and, in some way that is yet to be explained, counteracts the tendency to fatigue.[14] It is conceivable that the loss of this influence may explain the observations of Hunter, Royle, Kuntz and Kerper, and others who have found changes in tonus following sympathectomy. Impairment of the ability to resist fatigue would tend to diminish the amount of tonic contraction, especially under conditions in which fatigue is likely to develop. Uncertainty as to the conditions favoring fatigue, complexity of the circulatory changes resulting from sympathectomy, and possibly other obscure phenomena are factors that tend to confuse this problem and render it difficult to determine why some experiments are positive and some negative.

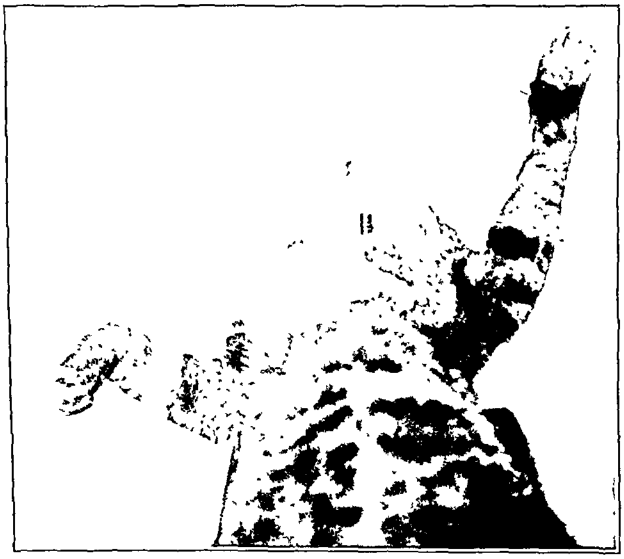

Fig. 3.—Appearance two hours after decerebration, six days after left stellate operation: persistent maintenance of greater rigidity in operated limb.

In any case, we feel that there is no justification for differentiating two distinct components, contractile and plastic, in the tonus of mammalian skeletal muscle. Sherrington is often quoted in support of this view, but he never made such a distinction. He merely called attention to the remarkable degree of plasticity in the decerebrate limb traceable to proprioceptive reflexes.

The relief of spasticity following ramisection has been slight in most of the cases reported as successful. Some operations have been entirely unsuccessful.[15] Many factors may enter into the success of such an operation. Besides the actual effect of interrupting the sympathetic nerve path there are other possible causes of improvement, such as exercises, mental suggestion, hospital care, and nursing. It is probably premature to ascribe the successes to the operation itself, and it may be that incidental features in the treatment will be found responsible for whatever good has been accomplished.

ANATOMY OF THE SYMPATHETIC NERVOUS SYSTEM

WITH REFERENCE TO SYMPATHECTOMY AND RAMISECTION *

S. W. RANSON
ST. LOUIS

The observations that have been made on the relation of the sympathetic nerves to disease have not yet been organized into a coherent system. And it is surprising that where the results obtained by the resection of these nerves are least open to question, they are not the results that one would have predicted from his knowledge of the structure and function of the sympathetic system. Probably many of the apparent contradictions will disappear as our knowledge becomes more precise. But although a great deal seems to have been accomplished and a means of surgical relief appears to have been found for what were previously hopeless conditions, work in this field should still be approached in the spirit of the investigator; i. e., with open minded skepticism.

The sympathetic nervous system is an aggregation of ganglions, nerves and plexuses through which the viscera, glands, heart, blood vessels and smooth muscle in other situations receive their innervation. The most conspicuous feature of the system is a pair of ganglionated nerve cords or sympathetic trunks which extend vertically through the neck, thorax and abdomen. Each sympathetic trunk is composed of a series of ganglions bound together by short nerve strands (fig. 1). Every spinal nerve is connected with the sympathetic trunk of its own side by one or more gray rami communicantes through which it receives sympathetic fibers for the control of blood vessels, sweat glands and smooth muscles of the hair follicles situated within the territory of its distribution. The majority of the nerve fibers taking origin in the ganglions of the sympathetic chain are distributed through the gray rami and the spinal nerves.

---

* From the Washington University Medical School.

* Read before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Nervous and Mental Diseases at the Seventy-Seventh Annual Session of the American Medical Association, Dallas, Texas, April, 1926.

The ganglions of the thoracic and abdominal portions of the chain are less concerned with visceral activity than with constriction of the peripheral blood vessels, erection of the hairs, and secretory activity of the sweat glands. But the upper thoracic and cervical ganglions bear a more intimate relation to the thoracic viscera, since they contain the cells of origin of postganglionic fibers for these viscera.

The thoracic and upper lumbar nerves are connected with the sympathetic chain by white as well as gray rami communicantes. These white rami contain both afferent and efferent fibers. The latter take origin from cells in the gray matter of the spinal cord, travel through the ventral root and white rami, and enter the sympathetic system, to terminate in synaptic relation with the nerve cells found in the sympathetic ganglions. They are often designated as preganglionic fibers, while those that arise in the ganglions and relay the impulses onward are called postganglionic. The gray rami contain postganglionic fibers; the white rami contain preganglionic fibers.

The majority of the preganglionic fibers turn either upward or downward in the sympathetic chain, and run for varying distances within it before ending in its ganglions. The cervical sympathetic trunk is composed exclusively of preganglionic efferent fibers, derived through the white rami from the upper thoracic nerves and ascending to terminate in the cervical sympathetic ganglions. The lumbar and sacral portions of the trunk are composed in the major part of descending fibers derived through the white rami from the lower thoracic and upper lumbar spinal nerves.

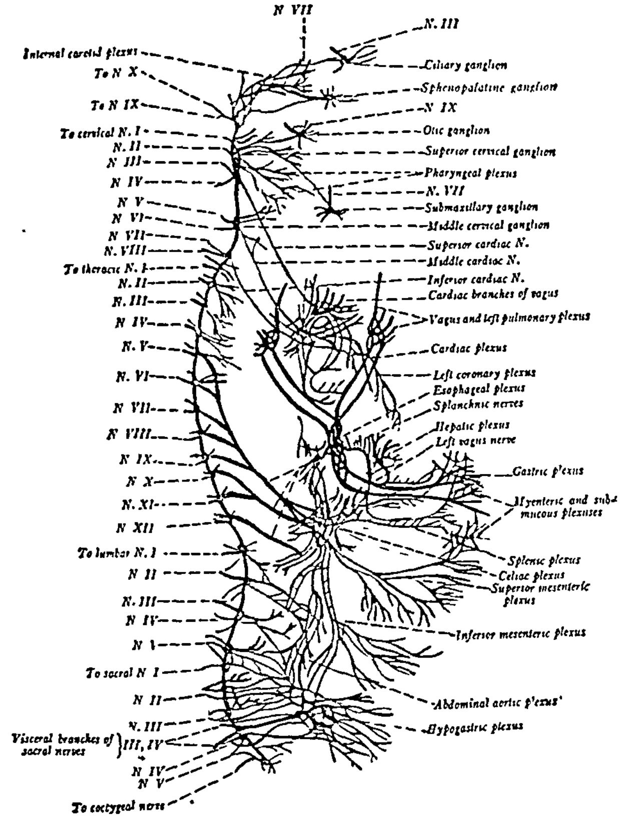

Fig. 1.—Diagram of the sympathetic nervous system. Those nerves and plexuses which are composed chiefly of fibers derived from cerebrospinal nerves are black; the sympathetic ganglions and the nerves and plexuses which are composed chiefly of fibers that arise in these ganglions are gray.

Those fibers of the white rami, which are concerned with the innervation of the abdominal viscera, pass into the splanchnic nerves and end in the celiac ganglion. These fibers reach the splanchnic nerves after passing through the lower half of the thoracic sympathetic chain; but they are not interrupted in the chain ganglions through which they pass.

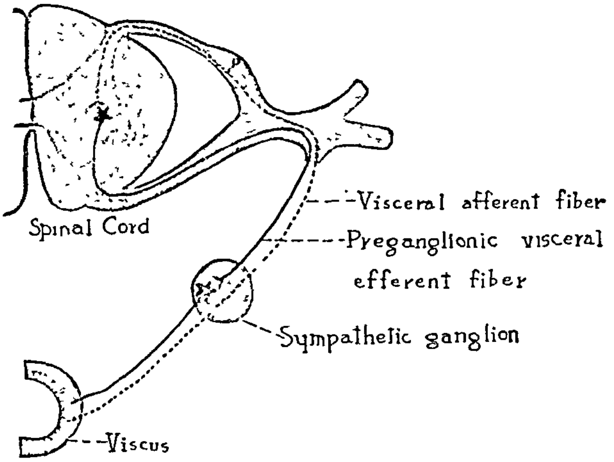

Fig. 2.—Diagram of a sympathetic reflex arc.

The sympathetic nervous system receives additional fibers from the spinal cord by way of the visceral branches of the third and fourth sacral nerves, and from the brain through certain of the cranial nerves.

There are, then, these three streams of preganglionic visceral efferent fibers: (1) the cranial stream from the third, seventh, ninth and tenth cranial nerves; (2) the thoracicolumbar stream, from the thoracic and upper lumbar spinal nerves by way of the white rami, and (3) the sacral stream from the second, third and fourth sacral nerves. The cranial and sacral streams belong to what is commonly called the parasympathetic system. Surgeons have confined their attention to the thoracicolumbar stream, i. e., to the sympathetic system proper, and we need not here consider the parasympathetic system in detail.

Most of the sympathetic nerves contain, in addition to the fibers already discussed, also sensory fibers, which convey impulses from the viscera to the spinal cord. These sensory fibers have their cells or origin in the spinal ganglions and reach the sympathetic system by way of the white rami. Visceral reflexes therefore travel arcs of at least three neurons each (fig 2). The impulses reach the spinal cord along visceral afferent fibers in the dorsal root and leave along preganglionic visceral efferent fibers in the ventral roots and white rami. These fibers end in sympathetic ganglions, and the impulses which they carry are relayed to involuntary muscle and glandular tissue by postganglionic fibers. The ganglions of the sympathetic trunk do not serve as reflex centers but only as relay stations in the conduction pathways from the spinal cord to the viscera.

The sensory fibers for the heart have recently acquired a new interest as a result of the relief of anginal attacks by cervical sympathectomy. In order to sever these fibers, Jonnesco[1] removed the middle and inferior cervical and the first thoracic ganglions of the left sympathetic chain in a case of severe angina pectoris. The patient, who was kept under observation for four years, remained free from anginal attacks.

---

[1] Jonnesco, T.: Bull. Acad. de méd., Paris 84: 93 (Oct. 5) 1920.

That this operation stops anginal pain can be readily understood, since the direction in which the pain radiates indicates that the fibers concerned reach the sympathetic system through the white rami of the upper three thoracic nerves on the left side (fig. 3). But the work of Coffey and Brown[2] seems to make this simple explanation untenable. These authors found that the same results can be obtained by sectioning the sympathetic trunk and superior cardiac nerve below the superior cervical ganglion or by excising this ganglion. At first they were inclined to believe that this demonstrated that the painful afferent impulses from the heart reached the brain through some of the connections of the superior cervical ganglion. A possible but highly improbable path for such impulses is indicated by the dotted line in figure 3. The good results which removal of the left superior cervical sympathetic ganglion have given in the hands of many surgeons are not easily explained on the basis of what is known concerning the innervation of the heart. Histologic, physiologic and clinical evidence makes it almost certain that in high cervical sympathectomy the afferent fibers from the heart are not injured.

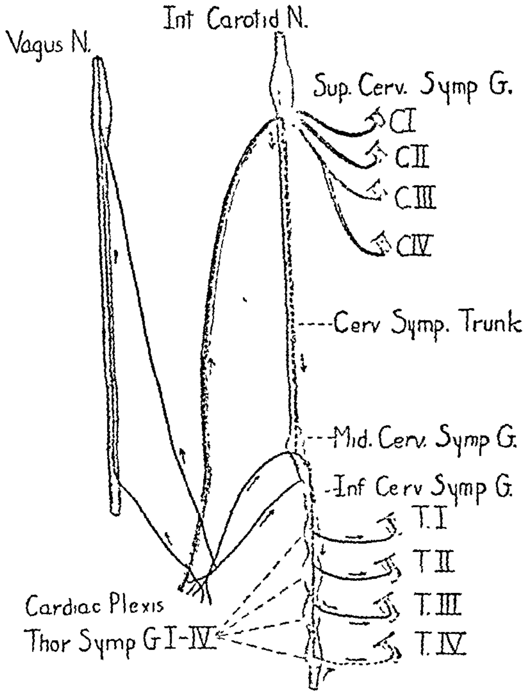

Fig. 3.—Diagram of the afferent pathways leading from the aortic plexus to the spinal cord and brain. The dotted lines represent a possible but highly improbable path.

Histologically, it is possible to trace sensory fibers through the sympathetic system because of their relatively large size. By this method Edgeworth,[3] working with the dog, and I,[4] working with the cat, have shown that the large sensory fibers in the cardiac plexus come from the vagus and from the upper three thoracic nerves. From these thoracic nerves, large fibers can be traced through the corresponding white rami and sympathetic trunk to the inferior and middle cervical sympathetic ganglions, and the nerves passing from those ganglions to the heart. No large sensory fibers are found in the cervical sympathetic trunk above the level of the middle cervical ganglion. The specimens removed at operation from patients suffering from angina pectoris usually show no large sensory fibers in either the cervical sympathetic trunk or the superior cardiac nerve. There is therefore every reason to believe that the sensory pathways for the heart in man are essentially the same as those in the cat and dog.

Physiologic evidence supports this conception of the sensory pathways. Langley[5] found that, if the connection between the vagus and the superior cervical sympathetic ganglion had previously been divided, stimulation of the cervical sympathetic trunk or of the superior cervical sympathetic ganglion never caused struggling or other signs of pain.

The clinical evidence, which is most important because it applies directly to man, is equally clear. The pain in angina pectoris is referred to the areas of cutaneous distribution of the first three thoracic nerves of the left side. This shows that the painful afferent impulses in angina reach the spinal cord along these nerves. Recently Jonnesco and Ionescu[6] have investigated the sensory pathways for the heart during operations for angina carried out under local anesthesia. They found that, if the upper connections between the vagus and sympathetic trunk had previously been severed, neither pain nor reflex responses could be obtained by stimulating the upper part of the cervical sympathetic trunk. But stimulation of cardiac nerves from the inferior cervical ganglion and from the annulus of Vieussens caused pain and reflex changes in respiratory rhythm. Avulsion of the first thoracic ganglion caused severe pain in the left arm. In a patient with angina pectoris, Schittenhelm and Kappis[7] injected procaine into the upper part of the sympathetic trunk without effect on the pain, but injection of the lower part caused the pain to disappear. Injection of the vagus gave no relief. During the course of an operation and before the first thoracic ganglion had been laid bare, one of Leriche's[8] patients had an anginal attack. Infiltration of the inferior cervical ganglion with procaine stopped the pain at once.

These clinical observations make it perfectly clear that in man, as in the cat, pain in the heart and aortic arch is mediated by way of the middle and inferior cardiac nerves through the lower cervical and upper thoracic portions of the sympathetic trunk, and thence along the upper thoracic white rami and the corresponding spinal nerves of the left side to the spinal cord.

In spite of the fact that there are no sensory fibers in the upper part of the cervical sympathetic trunk, resection of the superior cervical sympathetic ganglion has given good results in many cases of angina pectoris. To account for the relief which this operation gives is more than can be expected of anatomy. Let the problem be passed on to the physiologist.

It is true that sensory fibers reach the cardiac plexus by way of the cardiac branches of the vagus (fig. 3). But the afferent impulses which reach the brain from the heart by way of the vagus probably seldom give rise to pain but expend themselves in the production of reflexes, as, for example, the lowering of blood pressure as a result of the stimulation of the vagodepressor fibers ending in the arch of the aorta.

Eppinger and Hofer [9] have advocated section of the depressor branch of the vagus for the relief of angina pectoris. But it is doubtful whether this nerve has a separate existence in man. The uncertainty as to the existence and topography of this nerve is evident from the directions given for its identification. The vagus is dissected free up to the jugular foramen, and all of its branches are exposed and followed for some distance. Only those twigs which run free into the thorax, or those which, after separation from the vagus or from the superior laryngeal nerve, join the vagus again are considered as belonging to the depressor nerve. These directions are in themselves evidence that there is no well defined depressor nerve in man. It is possible that the twigs carrying depressor fibers might be identified by stimulation; but Eppinger and Hofer, out of consideration for their patients, failed to make the test in any of their cases. Odermatt [10] stimulated what he thought was the depressor, but this had no effect on the blood pressure. Wenckebach [11] admits that in many cases there is no clearly differentiated depressor nerve.

Through the work of Hunter [12] and Royle,[13] attention has recently been directed to the possibility that the tonus of skeletal muscle may be maintained by the sympathetic system. It is well known that the muscles are innervated by unmyelinated as well as myelinated fibers (Boeke and Kulchitsky). Degeneration experiments tend to show that part of the unmyelinated fibers take origin in the sympathetic ganglions. But observations, recently made by Hinsey and not yet published, prove that many, perhaps a majority of them, are not of sympathetic origin, since they are present in large numbers in the terminal branches of the motor nerve after degeneration of all of the sympathetic fibers. A review of the physiologic evidence for and against the sympathetic origin of tonus would be out of place in this paper. I wish to state, however, that the results of my experiments on cats have convinced me that the sympathetic nervous system is not responsible for the exaggerated tonus of the skeletal muscles which follows decerebration, or for that caused by tetanus toxin.

As yet no attempts have been made to interfere surgically with the craniosacral autonomic (parasympathetic) system by section of either the vagus or the visceral branches of the third and fourth sacral nerves. But section or, in certain cases, mere blocking of the splanchnic nerves offers attractive possibilities. These nerves contain sensory fibers and preganglionic visceral efferent fibers derived from the lower seven thoracic white rami communicantes (fig. 1). The preganglionic fibers end in the celiac ganglion, whence the impulses are relayed by postganglionic fibers along the periarterial plexuses composing the solar plexus. In this way inhibitory impulses are conveyed to the musculature of the stomach and intestines, and motor impulses to the pylorus. The splanchnics have been divided for atony and ptosis of the stomach by Bircher, and in two of his cases Hahn [14] made a roentgenologic study of the stomach. In both cases, the stomach returned to the normal shape and position and the pylorus became relaxed following the operation. In a patient with a diagnosis of gastric ulcer, Braun [15] found no signs of ulcer when the abdomen was opened. Because of the severe pain which the patient had been suffering, Braun sectioned the splanchnic nerves, with apparently good results.

Havlicek [16] blocked the splanchnic nerves in two cases of anuria in children with scarlet fever. His object was to interrupt temporarily the vasoconstrictor impulses to the arterioles in the kidney with the idea of stopping the spasm of these vessels, which was responsible for the anuria.

Periarterial sympathectomy, advocated by Leriche [17] as a cure for many painful and trophic disorders of the extremities, has caused renewed interest in the innervation of the blood vessels. It is said that after resection of the sympathetic plexus which surrounds the femoral or brachial artery the corresponding limb becomes hyperemic, old ulcers heal rapidly, and the pains of angiospasm, tender stumps and causalgia are relieved. These results seem to indicate that the vasoconstrictor and sensory fibers for the peripheral vessels accompany the main arterial trunks into the limbs. But this is in conflict with all that is known concerning the innervation of the blood vessels.

Vasoconstrictor impulses leave the spinal cord along preganglionic fibers, which reach the sympathetic system through the thoracic and upper lumbar spinal nerves and the white rami associated with them. The postganglionic vasoconstrictor fibers arise in the ganglions of the sympathetic chain, run by way of the gray rami communicantes to the spinal nerves, and follow these and their sensory branches to the subcutaneous tissue, where they are given off for the innervation of the small arteries and arterioles (fig. 4). Other fibers are given off from the larger nerves and reach the main arteries at various points along their course. A different arrangement holds for the vessels of the thoracic, abdominal and cranial cavities, since the vasoconstrictor fibers for these vessels do not join the spinal nerves but run directly to the vessels and accompany them to their distribution.

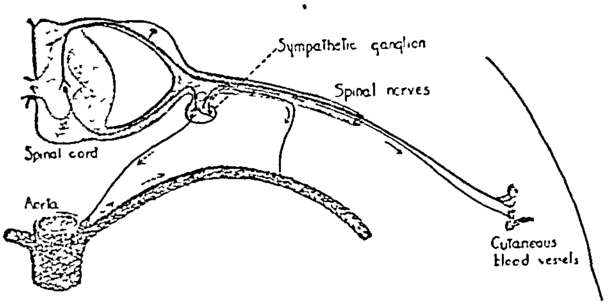

Fig. 4.—Diagram of the innervation of the blood vessels. The arrows with broken shafts indicate the path for vasoconstrictor impulses according to the theory of Leriche.

It is well established that in animals practically all the vasoconstrictor fibers for an extremity are found in the spinal nerves, and very few, if any, accompany the larger arteries for long distances toward the periphery. It had previously been universally conceded that they follow the same course in man. But the results of periarterial sympathectomy are out of harmony with this conception. In order to explain the hyperemia that results from this operation, Leriche assumes that in man the vasoconstrictor fibers for the cutaneous blood vessels have a course analogous to that taken by the fibers for the splanchnic vessels; i. e., they join the aorta or other large arteries in the thoracic and abdomi-

nal cavities and make their way to the periphery in the periarterial sympathetic plexuses. Against this assumption there should be recorded the observations of Kramer and Todd [18] showing that in man branches are given off by the large nerves to the principal arteries of the extremities at various points along their course. Furthermore, it is improbable that there is any fundamental difference in the innervation of the blood vessels in man and the laboratory animals.

It will be evident from the foregoing discussion that no satisfactory explanation of the hyperemia following periarterial sympathectomy has yet been presented. It is equally impossible to explain the relief from pain which some patients experience after this operation. That there are sensory fibers supplying the blood vessels is well known, but these for the most part at least run centrally in the spinal nerves, and there is no reason to believe that they run in the periarterial sympathic plexuses for any considerable distance.[19] Perhaps the relief from pain may depend on the hyperemia and resultant improved peripheral nutrition.

THE EFFECT OF SYMPATHECTOMY ON SPASTIC PARALYSIS OF THE EXTREMITIES [*]

LOYAL DAVIS, M.D.
AND
ALLEN B. KANAVEL, M.D.
CHICAGO

For many years, evidence has been offered both to prove and to disprove the dual innervation of striated muscle by the cerebrospinal and sympathetic nervous systems. The question remained more or less an academic one, in the discussion of which anatomists and physiologists were the leading figures. Recently, however, the surgeon has entered the field mainly as a result of the suggestion by Royle, supported by Hunter, that the spasticity of paralyzed extremities might be decreased by surgically attacking the sympathetic innervation to the muscles.

The basis for such surgical therapy may be stated rather briefly. It is assumed that striated muscle has a dual innervation from the sympathetic and cerebrospinal nervous systems. It is predicated that the normal tonus of skeletal muscle may be divided into two components; namely, a contractile and a plastic element. Further, that in spastic extremities there is an increase of the plastic component of tone. Finally, it is assumed that the sympathetic innervation to striated muscle subserves this plastic element of tone. It becomes obvious that following such a line of reasoning leads to the conclusion that, to decrease spasticity or hypertonus in an extremity, it becomes necessary to remove the sympathetic innervation to the muscles involved.

Such an hypothesis depends on several important principles, each of which must be examined carefully and should be firmly established before a clinical application is made. Otherwise our surgical therapeusis may outdistance our fundamental knowledge, and we may add more confusion to the surgery of the sympathetic nervous system, which has already suffered from a tendency toward clinical empiricism.

SYMPATHETIC INNERVATION OF SKELETAL MUSCLES

The definite establishment of the fact that skeletal muscle has a sympathetic innervation underlies the entire problem of the relation of the sympathetic system to increased tone in the muscles of an extremity. Further, if we grant that such a supply is present, we must know absolutely that such an innervation initiates, maintains or in some manner influences muscle tone.

In 1879, Tschiriew [1] demonstrated two systems of motor nerve fibers to striated muscle. In a study of the snake he pointed out the presence of nonmedullated nerve fibers with characteristic end organs, in addition to the usual medullated nerve fiber motor end plates. It should be noted, however, that the nonmedullated nerve fibers which ended typically in a grapelike ramification could be traced as a branch of a medullated nerve fiber and were thus shown not to be entirely independent structures. Three years later, Bremer [2] described fine unmyelinated nerve fibers entering the motor end plates in frogs and lizards. Some of these nonmedullated fibers had lost their myelin in their course in the muscle; some were branches of medullated fibers, but others arose from an unmyelinated plexus although they could not be traced farther centrally. Later, Perroncito [3] came to similar conclusions, and it remained for Boeke [4] to state that the endings described by these workers were not of independent origin, as they had stated, but that still other nerve endings, which he designated as "accessory," were the actual terminations of the nonmedullated fibers of sympathetic origin. Boeke described a nerve fiber and ending of each type situated hypolemmaly on a single muscle fiber. That is, a medullated system of fibers and end organs of cerebrospinal origin and a nonmedullated system of fibers and end organs of sympathetic origin. This author sectioned the oculomotor nerve near the brain stem in cats and found degeneration of both medullated and nonmedullated fibers in the levator palpebral superioris muscle. Some nonmedullated fibers remained intact, and these he regarded as of sympathetic origin.

Kulchitsky [5] repeated Tschiriew's work on the snake and stated that a single muscle fiber receives only one motor nerve ending. He pointed out that some muscle fibers receive an epilemmal ending derived from a nonmedullated nerve fiber, while others receive a hypolemmally placed medullated nerve fiber. Using Kulchitsky's personal preparations, Dart [6] confirmed the presence of two types of nerve endings but differed somewhat from the former in an interpretation of the method of innervation of the muscle fibers. Kuntz and Kerper [7] found unmyelinated nerve fibers of sympathetic origin in the intercostal muscles of dogs after they allowed time for degeneration of the somatic nerves to these muscles. Garven [8] has only recently confirmed the presence of Boeke's accessory fibers and endings, which he stated were quite independent and were of sympathetic origin.

As Langley [9] has stated, if all striated muscles contain sympathetic nerve endings, it is unusual that they cannot be seen in methylene blue preparations of the frog's sartorius muscle, in which somatic nerve endings and nerve fibers around blood vessels are brought out with ease.

[9] Langley, J N.: The Autonomic Nervous System, Cambridge, Heffer & Co., 1921.

Therefore, in spite of evident contradictory facts and from purely histologic evidence based on studies of sections stained by the silver impregnation methods, it is probable that all striated muscle contains two types of nerve fiber endings. The larger medullated fibers are those derived from the cerebrospinal system; while the smaller, unmyelinated fibers which end in rings, loops or nets either within the sarcoplasm of a typical end plate, or as small independent end plates, are derived from the sympathetic nervous system. However, these facts afford no conclusive evidence of the function of these fibers.

On the basis of these facts, Hunter and Royle[10] formulated the hypothesis that there are two groups of muscle fibers with distinct motor innervation and separate and specific function. They stated that the cerebrospinal motor nerve endings were concerned in ordinary muscle movements and with a component of muscle tone which they termed "contractile." They believed the sympathetic or nonmedullated nerve endings to be related to the maintenance of a second element of muscle tone, the so-called plastic tone, which is enormously increased in spastic extremities.

COMPONENTS OF MUSCLE TONE

Based on Boeke's histologic work, Langelaan[11] proposed that each skeletal muscle fiber has a dual function as well as a dual structure. He predicated the existence of a sarcoplasm innervated by the sympathetic system. In this mass lies the striated tissue, which receives its innervation from the cerebrospinal nervous system. As a corollary, he divided muscle tone into a plastic element dependent on the sarcoplasm and its sympathetic innervation, and a contractile component affected by the striated apparatus and innervated by the cerebrospinal nerves. Langelaan attempted experimentally to demonstrate the presence of these two types of muscle tone. He measured the elasticity and plasticity of muscle and pointed out the differences in the two kinds of muscular activity. Forbes[12] has aptly stated that such differences may result from the various ways in which muscle fibers contract in different types of reflexes, and it need not necessarily be assumed that there are two types of muscle tone. Hunter and Royle differed somewhat from Langelaan in that they believed that, instead of one muscle fiber subserving two elements of tone, there are two sets of muscle fibers within any given muscle. The one initiates contractile tone and receives its innervation from the cerebrospinal system, and the second set of fibers serve for plastic tone and are innervated by the sympathetic nervous system. They have interpreted plastic tone as that element which is inhibited during movement and which in a normal muscle maintains an attitude against gravity. It follows that when plastic tone is abolished, the limb passively assumes an attitude determined by gravity, and when increased, as in spasticity, the limb tends to maintain any given position imposed on it during an exhibition of contractile tone. Carrying this idea to the decerebrated animal, they have stated that the extended position of the extremities assumed following decerebration is an evidence of contractile tone, while the maintenance of that posture is the function of plastic tone.

It will be apparent at once that such a theory of muscle tone is in direct opposition to Sherrington's conception of tone as a reflex reaction, the stimulus for which comes from a proprioceptive source and the purpose of which is to maintain posture. Sherrington believed that there are two reflex pathways concerned in the innervation of striated muscle. The one has to do with initiating and regulating the state of tension within the muscle itself, the reflex reactions of which are tonic in character. Stimulation of the second, or phasic, reflex pathway results in reactions that are a series of repeated but short-lived movements. Both the tonic and the phasic pathways are acted on by the cerebral motor cortex, and both employ the striated muscle and the neurons of the anterior horn cells of the spinal cord as the single effector mechanism. The extensor groups of muscles are mainly concerned in the effector side of the tonic reflex pathway, and the state of muscle tone resulting affords the basis for posture. The stimuli necessary to produce an adequate reaction from this reflex arc arise within the muscle iself and within the otolith organs of the labyrinths and in proprioceptive centers in the entire body musculature. The effective stimulus for the proprioceptive center is muscle stretching, while a change in the relation of the otolith organs to the horizontal plane in space acts as the adequate stimulus. In contrast, the phasic reflex arc employs flexor groups of muscles. The centers for the phasic system lie in the spinal cord, whereas centers in the brain stem govern the tonic pathway. It is clear that there must be perfect harmony and coordination between these two reflex systems governing muscle tone. Without this complemental cooperation, smoothly coordinated muscular movements would be lacking. It is this phase of the subject to which Sherrington's theory of reciprocal innervation applies.

It is obvious that the hypothesis formulated by Langelaan, Hunter and Royle radically breaks away from many well proved and established physiologic facts in regard to muscle tone. Incontrovertible evidence must be given before such a theory can be accepted in whole and applied clinically.

EXPERIMENTAL EVIDENCE

Since they believed that plastic and contractile tone are innervated by separate systems, Royle and Hunter attempted experimentally to isolate these functional elements. They removed the lumbar sympathetic rami on one side of a goat, and after a considerable interval performed decerebration by the usual guillotine method, which, as is well known, is accompanied by considerable hemorrhage, shock and inaccuracy in determining the exact level of decerebration. They found that under such experimental conditions the limb so denervated fell into an abducted, semiflexed attitude, while on the unaffected side extensor rigidity was marked. This result was explained as due to a loss of plastic tone. The second type of experiment performed by these authors consisted in an endeavor to isolate plastic tone. They used the fowl as an experimental animal because of the anatomic separation of the cerebrospinal and sympathetic innervation to the wings. They severed the cervical posterior roots, thus leaving the sympathetic supply intact and consequently assumed they had removed contractile tone and had retained plastic tone.

[11] Langelaan, J. W.: Brain **38**: 325, 1915; **45**: 434, 1922.

[12] Forbes, Alexander, in discussion on Crothers, Bronson: Cases Treated by Sympathetic Ramisection, Arch. Neurol. & Psychiat. **13**: 639 (May) 1925.

Trendelenburg[13] has recorded careful experiments of a similar nature. This investigator carried out very thorough anatomic and histologic controls on his birds after they had been killed. He performed extensive divisions of the cervical and thoracic posterior roots, which of necessity removed both somatic and sympathetic efferent innervation. Trendelenburg concluded that such denervation of a single wing produced no drooping or loss of voluntary or reflex movements. The most common and logical objection offered to Royle and Hunter's work is that in all probability they produced injury to the ventral as well as to the posterior roots.

With Pollock,[14] we repeated the work of Royle and Hunter with respect to the influence of sympathetic denervation on the pattern of decerebrate rigidity. Cats were employed as experimental animals. Hunter regarded the cat as an unsuitable animal for the investigation of problems of tone, on the ground that the variability of contractile tone masked the loss of plastic tone. This animal in Sherrington's and Magnus and de Kleijn's hands has proved to be of great value in working out just such problems. Eighteen animals were operated on and were kept under observation for periods of from two to nine weeks. No changes in the character of voluntary or reflex movements were observed. Twelve cats were decerebrated by ligation of the basilar artery at a selected level and simultaneous ligation of the common carotids. The fact that animals so operated on present active Magnus and de Kleijn phenomena forty-eight hours after ligation precludes the objection of a hypertonus due to asphyxial spasm. In all these animals the onset and maintenance of decerebrate rigidity was exactly similar in all four extremities, including the one previously deprived of its sympathetic innervation. Other workers, including Cobb,[15] Barenne,[16] Kuno,[17] Lopez,[18] von Bruck,[18] von Rijnberk[19] and Towers,[20] arrived at a similar conclusion; namely, that normal muscle tone and the pattern of decerebrate rigidity do not depend on sympathetic innervation.

Recently Ranson[21] has applied continuously a solution of nicotine to the posterior roots and spinal ganglions of a cat after the onset and maintenance of decerebrate rigidity. He noted that the rigidity in the corresponding limb disappeared within ten minutes, although the reflex activity remained. He believes that the impulses responsible for plastic tone pass through synapses of a sympathetic character in the spinal ganglions; that is, through the pericellular nerve networks which surround spinal ganglion cells. This would mean that such impulses are relayed to the muscles, as vasodilator impulses are to the skin, by sensory fibers acting antidromically or by true postganglionic fibers.

CLINICAL EVIDENCE

Many difficulties have arisen in the experimental identification and isolation of contractile and plastic tone. It is obvious that a like difficulty is present if we attempt to say from clinical examination that in one case plastic tone is increased and in another it is decreased. The lack of any standard of comparison or precise method of measurement adds to the confusion.

Hunter and Royle applied their theories of tone to selected cases of spastic paralysis and suggested sympathetic ramisectomy to relieve these patients of the presence of excessive plastic tone. They pointed out certain criteria which should be observed in the selection of cases suitable for operation. Preferably these methods to detect increase of plastic tone should be available at the bedside and should be easily applied. The increase of resistance of the muscles to passive movements, the "hung-up" or steplike tendon reflex, and the presence of sufficient mentality to carry out a program of reeducation are the main indications given by these authors.

After considerable clinical and operative work, Hunter and Royle stated that patients with an increase in plastic tone as the result of paralysis agitans, postencephalitic Parkinson's disease and degenerative or traumatic lesions of the spinal cord were unsuitable for operation. Consequently, they confined their attention to cases of Little's disease, traumatic cerebral cortical lesions and vascular cortical lesions. They have reported definite improvement in such patients after removal of the sympathetic rami.

With Pollock, we have performed ramisectomy and in some cases have completely removed the sympathetic chains in the cervical or lumbar regions, in cases of paralysis agitans, postencephalitic Parkinson's disease, spinal lateral sclerosis, cerebral hemiplegia, Little's disease and spastic paraplegia in extension from a traumatic spinal cord lesion. All these patients were normal mentally and had sufficient cerebral motor control to justify a removal of plastic tone. Careful kymographic and electromyographic records of reflex and voluntary actions and response to faradic stimulation were taken before and after operation. We also made complete roentgen-ray studies to determine the effect of interruption of the abdominal sympathetic trunk on the movements of the gastro-intestinal tract. Motion pictures of the gait, range of active movements, resistance to passive movements and reflexes were made of each of the patients. All the patients exhibited shortening and lengthening reactions on reflex stimulation. The tendon reflexes showed a "hung-up" characteristic; some patients, of course exhibited this more than others.

In our operations we employed several means of approach. We removed the entire cervical sympathetic trunk and its ganglions, including the stellate ganglion; we removed the latter alone and we have removed the abdominal sympathetic trunk on one or both sides from the second lumbar ganglion to and including the fourth lumbar ganglion. We have performed the latter operation both by the lumbar approach advocated by Royle and through a midline abdominal incision.

In order that we might properly evaluate the effects of sympathectomy, we purposely refrained from suggesting to the patient that he might be improved. We did not institute physiotherapy until a reasonable time had elapsed after operation, so that any results obtained could be ascribed alone to the surgical procedure.

We have given elsewhere the graphic records and results of our operations in these cases. We have examined them again eighteen months after operation, and our findings confirm our original conclusions. We are agreed with Hunter and Royle that no benefit from such an [illegible] results in cases of paralysis agitans, [illegible] rkinson's disease and degenerative or traumatic lesions of the spinal cord. We must also add that we have been unable to observe or record any improvement in the cases of Little's disease or cerebral hemiplegia due to a vascular lesion. Consequently, our conclusions have been entirely negative and have failed completely to offer any confirmation of Royle and Hunter's work.

COMMENT

Tone is a property of muscle, the components of which are today incompletely known and the physiology of which is poorly understood.

Three mechanisms may be accepted as being concerned in hypertonicity: the corticospinal tract, the extrapyramidal system, represented largely by the striate body, and the brain stem mechanism. It may be possible that a fourth mechanism may play a considerable part; namely, cerebellar cocontraction. Finally, there may be some peripheral mechanism of muscle metabolism, related to tone and particularly active in such diseases as tetany, in which condition muscular cramps, changes in electric excitability and irritability of muscles are found.

It has been suggested that that element of muscle tone which is related to the postural, in contradistinction to the kinetic, system is mediated by the sympathetic nervous system through a high reflex arc in the pons and a lower one in the cord. The afferent and efferent limbs of the lower arc would arise and terminate in the sarcoplasm of skeletal muscle. It would seem to be unreasonable to assume that such a reflex pathway would serve all of the functional mechanisms just mentioned. If it be true, then sympathectomy should abolish that tone which in spasticity is due to hyperactivity of postural tone. It has been stated that this type of tone may be recognized by characteristics which were described by Sherrington as the plastic tone found in decerebrate animals and which are present in all cases of hemiplegia, cerebral diplegia of pyramidal tract origin and paraplegia in extension. We have been unable to record any graphic changes in the condition of muscle tone in any of the clinical lesions mentioned above, following removal of the sympathetic innervation to an extremity. We have also been unable to record or observe any changes in the spasticity produced by the release of function in striatal disease or in traumatic or degenerative lesions of the spinal cord which have for the most part involved the lateral pyramidal tracts.

If hypertonicity is the result of removal of the inhibition of corticospinal influences alone or in combination with hopothetic cerebral sympathetic fibers, it seems strange that complete removal of the brain cephalad to the red nucleus does not produce spasticity in animals. If, on the other hand, hypertonicity is due alone to removal of the influences of the corticospinal tract and the upper levels of a sympathetic reflex arc, it is difficult to explain why complete section of the spinal cord fails to produce spasticity. It cannot be because of spinal shock or diaschisis because of the existence of mass reflexes in a so-called isolated segment of the cord. It would seem that a large amount of investigation is necessary to show why incomplete lesions do, and complete lesions, with the exception of those in the brain stem, do not produce hypertonicity. If there are a number of factors concerned with increase of tone, then it is necessary quantitatively to measure the diminution of tone, if any, that results from removal of the sympathetic nerve supply. This is necessary to obviate the inaccurate interpretation of any clinical improvement as due to lessened muscle tone, when other factors may be involved. We feel that changes in muscle tone cannot be determined by the ordinary clinical examination, by the statements of patients or even by clinical results which have before been produced by hope and reeducation. It must be demonstrated by careful physiologic research and objective measurement that certain changes have occurred.

It is possible that the sympathetic nervous system may have some function relating to muscle tone; or, better, it may have some function dealing with the metabolism of muscles so that under certain conditions the contractility of a muscle may be changed by the removal of sympathetic impulses. Such a function may deal with colloidal chemistry. It may be that the increased vascularity that follows sympathectomy may influence the quality of muscle tone. It may also be possible that, because of modified metabolism or circulation, the character of the afferent impulses from muscles is changed; as an example, the occurrence of pain in an anemic muscle. As Pollock has suggested, it may further be possible that certain apparent changes in range of motion may be due to vasodilatation in the synovial membrane and a concomitant increase in secretion of synovial fluid. Under any of these conditions, the changes produced by sympathectomy will probably be found to be temporary, as are the vasomotor skin changes.

CONCLUSIONS

1. Histologic evidence points to the dual innervation of skeletal muscle from the cerebrospinal and sympathetic nervous systems.
2. Experimental removal of the sympathetic trunks in cats produces no effect on normal tone that can be observed or recorded.
3. The onset and maintenance of decerebrate rigidity in cats is unchanged after the removal of the sympathetic innervation to an extremity. With the exception of Royle's work on goats, the evidence in the literature is in agreement on this point.
4. The problem of muscle tone is extremely complicated, and one or all of several mechanisms may be responsible for changes in muscle tone. At present there is no accurate clinical method for measuring changes in muscle tone. Lengthening and shortening reactions and "hung-up" reflexes alone are insufficient indications for operation.
5. Kymographic tracings of tendon reflexes, faradic stimulation, active and passive motions and tremors before and after removal of the sympathetic nerve supply have shown no change in cases of paralysis agitans; postencephalitic Parkinson's disease; system degenerations of the spinal cord, such as lateral sclerosis; traumatic lesions of the spinal cord; cerebral hemiplegia, and Little's disease.
6. The sympathetic nervous system may have some function dealing with the metabolism of muscle, so that under certain conditions the contractility of a muscle may be changed by the removal of sympathetic impulses. Such a function would probably be chemical in nature.

ARACHNIDISM

A STUDY IN SPIDER POISONING *

EMIL BOGEN, M.D.
LOS ANGELES

The popular belief that spider bites are poisonous has found little support in scientific writings. Entomologists and arachnologists have been almost unanimous in asserting the innocuous nature of spiders, and medical men have been accused of unscientific readiness to accept popular reports without attempting to establish the truth or falsity of the facts claimed. A spider bite, as any other wound, may easily become infected; thus, definite cases of tetanus, anthrax, erysipelas, cellulitis and septicemia, proved at necropsy and by bacteriologic examinations, have been reported as arising from spider bites by Lawrence, Garcia, Wight, Davison and Presley. Moreover, the very measures adopted for the treatment of a spider bite may in themselves be the cause of many of the symptoms reported, as the local sloughs following the injection of ammonia water or the application of caustics, or the symptoms of intoxication following the free imbibition of "stimulants." The possibility of coincidence must also be borne in mind, and the relationship between a spider bite and a subsequent pathologic condition cannot be determined solely by a "post hoc, ergo propter hoc" reasoning in a single case.

Nevertheless, the almost universal belief in the poisonousness of spider bites among peoples separated by every difference in longitude and civilization, and the persistent reports of serious results from spider bites, are not entirely lacking in foundation. The large, hairy tarantula is, to the lay mind, the most dangerous of the poisonous varieties, although authentic cases only partially support its terrible reputation.

There is abundant evidence that the bite of the shiny black *Latrodectus* is attended with severe systemic poisoning. Virtual epidemics of arachnidism from the bite of *Latrodectus malmignatus* were reported in Spain in 1830, 1833, and 1841, and similar cases have since been described by many observers in France, Italy and Corsica. Other epidemics due to *Latrodectus karakurt* were reported from the Russian provinces of the Kirghiz Steppes in which animals as well as human beings were the victims. More than a dozen writers have recorded severe consequences from the bite of *Latrodectus scelio*, the "katipo" of New Zealand and Australia, and from the "mena vodi" of Madagascar. In South America, clinical and laboratory reports from more than thirty authors have established spider bite poisoning as a clinical entity. During the last hundred years more than 150 cases of poisonous spider bites have been reported by thirty-three physicians in the United States, and fifteen cases of this malady have been studied at the Los Angeles General Hospital during the last decade.

LATRODECTUS MACTANS

Latrodectus mactans is probably the only poisonous spider in the United States. Besides its many scientific synonyms, it has many popular nicknames, as the "black widow," the "shoe-button" spider, the "hourglass" spider, the "T dot" spider, and the "po-ko-moo." It is a shiny, coal-black spider, usually brilliantly marked with red or yellow or both. The markings vary greatly, the most constant being a bright red patch, shaped somewhat like an hourglass, on the ventral surface of the abdomen. The female, which is always the one responsible for the bites reported, is often half an inch in length when fully grown, and may stretch its long, glossy legs over a spread of as much as 2 inches. The globose abdomen, somewhat larger than the cephalothorax, resembles a black shoe button, although it may have one or more red spots along the middle of the back, and over the spinnerets, in addition to the large ventral patch. The male is much smaller than the female, and is even more conspicuously marked, having, in addition to the marks of the female, four pairs of stripes along the sides of the abdomen. The young spiders are much lighter in color, and gradually don the glossy black coat in a series of molts during a period of about forty days.

Previous studies of spider poison are highly conflicting and confusing. We have repeated many of the reported experiments with *Latrodectus mactans.* Macerated suspensions of the spider failed to show any hemolytic power in vitro, and were without effect when injected. The bite of the spider, however, produced in young white rats severe symptoms often leading to death.

The black widow, so called from the custom of eating its mate, builds its coarse and irregular dark web in dimly lighted places where it may be undisturbed. Occasionally it is found under stones or pieces of wood, or in holes in the ground, in old stumps or in bushes, more often in the rafters and corners, under the floors and in the attics of little used frame houses, and in the dark corners of barns and other outbuildings, and it has been frequently seen in outdoor privies, where it often builds its web across the seat of the toilet. Although it is encountered mainly in the southern half of the United States, from the Atlantic to the Pacific coast, specimens have been reported also from such Northern states as New Hampshire, Pennsylvania and Ohio.

REVIEW OF ONE HUNDRED AND FIFTY CASES PREVIOUSLY REPORTED

More than two thirds of the reported cases of spider bite poisoning occurred in California, but cases were reported from more than a dozen other states. Most of the victims were males, and the majority were bitten on the penis or adjacent parts while sitting in an outdoor privy. The spider was caught and positively identified in only a dozen cases, but the description of it as a black spider, and the frequent mention of the red spot on the abdomen leaves little room for doubt of the species in most of the others. A stinging or sticking sensation was noted at the time of the bite, but this soon disappeared, and except for a tiny red spot sometimes reported, there was no mark or swelling to indicate the site of the bite. Acute pain, however, was present in some form in every case. It appeared in from a quarter to a half an hour, reached its acme in less than two hours, and persisted for more than six hours undiminished, then subsided in the course of a day or two, but did not disappear for several days, and was variously described as severe, intense, aching, agonizing, excruciating and paroxysmal. The pain spread from the region of the bite by contiguity; thus, the patients bitten on the penis generally had pain in the groin and then in the abdomen and back, while those bitten on the wrist had pain in the arm and chest before it reached the abdomen. The final distribution of the pain, however, was fairly uniform, wherever the initial lesion might be, being most often localized in the abdomen and legs, frequently also in the back, chest, groins and hips, and "all over," and less often in the arms, shoulders and head.

---

* Read before the Section on Pharmacology at the Seventy-Seventh Annual Session of the American Medical Association, Dallas, Texas, April, 1926.

In addition to the acute pain, displayed in most cases by writhing, rolling, doubling up, muscle spasms and paroxysms, many other symptoms are enumerated, including, in the order of frequency, profuse cold perspiration, restlessness and anxiety, difficult breathing, nausea and anorexia, vomiting, constipation, cyanosis, delirium, prostration or shock, insomnia, disturbances of speech, acute urinary retention, paralyses, convulsions, localized swelling of the bitten part or other parts of the body, a macular skin eruption, chills, vertigo and jaundice. An extreme boardlike rigidity of the abdomen was the most striking physical finding, but abdominal tenderness was usually not mentioned. Tremors, muscle twitching and paresthesias were present in some cases, and priapism was occasionally observed. A slow pulse was noted in a number of cases, but a rapid one was just as common.

General weakness, numbness or tingling of the legs, or even actual bodily pains often remained throughout a long convalescence. Twelve deaths were reported; but only a few of them, as in the cases of Mr. Dick in North Carolina, Dr. Reese in Oklahoma, and Dr. Clark in California, have been described in detail. In the latter cases the symptoms appear to have been the usual ones, perhaps unusually severe, and death ensued in from fourteen to thirty-two hours.

Seldom in medicine will one find a greater diversity of treatment than in the recorded cases of spider bites. More than seventy-five different remedies have been administered for this condition, each with the greatest confidence that this was the line of treatment to give the patient the greatest benefit. The sheet anchors of therapy, however, have been morphine, whisky or brandy, ammonia water or spirit of ammonia, atropine, magnesium sulphate, hot baths and fomentations, enemas, bleeding, opium or laudanum, strychnine, camphor and potassium permanganate. Among other therapeutic measures administered were calomel, cantharides, catheterizations, castor oil, cocaine, arsenic, amber, antimony, acetylsalicylic acid, aconitine, belladonna, mercuric chloride, boneset, Dover's powders, Darby's fluid, echinacea, edgeweed, elaterium, glonoin, scopolamine, hoarhound, ipecac, lavender, mustard plasters, milk, magnesium phosphate, nitroglycerin, olive oil, potassium acetate, iodide and carbonate, phenol (carbolic acid), plantain, rue, quinine, sinapisms, spirits of turpentine, squirrel's ear, senna, sodium chloride, tansy, antimony and potassium tartrate, tobacco poultice, valerian, volatile liniment and Wizard Oil.

FIFTEEN ADDITIONAL CASES

The fifteen patients suffering from spider bite treated at the Los Angeles General Hospital were all males, ranging from 2 to 65 years of age. Most of the bites occurred after dark, in the late summer and early fall. Two thirds of the patients were bitten on the penis while sitting in an outdoor toilet. One or two tiny red spots were seen at the site of the bite in half of the cases, but these soon disappeared, and in no case was any swelling or inflammatory reaction manifested. Pain was in each instance the chief complaint, arising almost immediately in most cases and reaching its greatest severity in from one to two hours. It began to subside in from four to eight hours, but the severe symptoms were present for from twelve to twenty-four hours, and complete relief was not achieved for several days. The pain was described as acute, severe, continuous, cramping, throbbing or aching, sometimes sharp and sometimes dull, and was localized in the abdomen and legs in nearly all cases, but was also felt in the chest, arms, penis, groins, back and "all over" in many. Profuse perspiration, restlessness, nausea and vomiting, constipation, and rapid or difficult breathing were the chief symptoms noted, but vertigo, ataxia, chills, acute urinary retention, localized edema in the face or in the feet, and persistent hiccup were also recorded. On admission, the patients were writhing, tossing or moaning in the agony of pain. The abdomen was tense, with an extreme boardlike rigidity, but abdominal tenderness was noted in only three cases. The reflexes were increased in half the cases examined, especially the knee jerk, and tremors and muscle twitching were often present. Priapism was also noted.

Initial subnormal temperature followed by a mild fever was an almost constant feature in these cases, but in only one case did the temperature exceed 101 F. The pulse was generally slow as compared with the temperature, being below 66 in more than half of the patients at some time during their first days in the hospital. The respiration, however, was usually slightly accelerated on admission, but soon came down to a normal rate. The blood pressure was always elevated, averaging 150 mm. of mercury systolic with 87 mm. diastolic, but dropped rapidly on later readings. Leukocytosis was present in almost every case, averaging 14,800 in the cases examined on the first day in the hospital, the highest count being 21,800, but dropping to an average of 10,700 in the cases examined several days later, the lowest being 5,900. There was generally a relative polymorphonuclear leukocytosis, averaging 80 per cent in the cases recorded. The red blood count was variable, being often above normal, and the color index when calculated was about 1. Four of the patients in this series had positive Wassermann reactions. A trace of albumin and a few hyaline or granular casts were found in the urine in six cases, and blood was found in the urine in one. Almost all of the patients had obstinate constipation, causing them to go one or two days without a bowel movement while in the hospital, and two developed acute urinary retention, requiring catheterization.

TREATMENT

The treatment at the General Hospital has consisted mainly of (1) sedatives, such as morphine or codeine, which had to be given in larger doses than usual to secure results, bromides, chloral, barbital and hot applications; (2) stimulants, such as aromatic spirit of ammonia, caffeine and strychnine, and (3) eliminative measures, such as purgation with magnesium citrate or sulphate, castor oil or calomel, enemas, catheterization and gastric lavage.

Little is known about antibody formation to spider venom, but the experiments of Baerg and others indicate that one bite confers a degree of immunity, and so it was suggested that some form of specific serum treatment be attempted. Accordingly, 20 cc. of blood was taken from a patient who had recovered from a severe poisonous spider bite and injected intramuscularly into a man who had just entered the hospital in the agony of pain from a spider bite. Since he improved following the injection, the same procedure has been followed in three other cases since then, and in each instance relief was experienced in a much shorter time than would have been expected without such treatment. This was especially noted in the cases treated within a few hours after the bite was received. The results, while not conclusive, are sufficiently encouraging to warrant the continuation of the use of convalescent serum in every case that is admitted following a poisonous spider bite, and a supply of convalescent serum is now kept at the hospital for this purpose.

CONCLUSION

Arachnidism, or spider bite poisoning, presents a clinical entity so striking that the diagnosis should easily be made, once the possibility is considered. One hundred and fifty cases have previously been reported in the United States, and fifteen cases have been seen at the Los Angeles General Hospital; but undoubtedly many more cases occur and may even pass unrecognized. Constant findings in this condition are a history of a bite by a black spider, followed by excruciating pain, mainly in the legs and abdomen, extreme abdominal rigidity, high blood pressure, elevation of temperature and a polymorphonuclear leukocytosis. Large doses of opiates and the application of heat are our main symptomatic remedies, but convalescent serum seems to be of specific therapeutic value.

LOCAL ANESTHESIA IN THE REDUCTION OF FRACTURES *

IRA COHEN, M.D.
NEW YORK

Since 1885, when Conway [1] first advocated the use of cocaine in the reduction of fractures and dislocations, the only reference to the subject in American medical writings is an article by Cumston,[2] in 1918. Conway reported three cases of Colles' fractures and one of posterior dislocation of both bones at the elbow reduced under local anesthesia. The European literature contains series of cases reported by various authors. Reclus,[3] in 1903, made use of the method to transport in comfort a patient with a fracture of the femur, and found that a half hour later the anesthesia was sufficient to allow of the reduction of the fracture. Lerda [4] reported thirty cases in 1907, and the following year Quenu [5] described its use in fifteen cases. Braun [6] detailed fifty cases in which he used local infiltration twenty-three times and either brachial or other forms of conduction anesthesia in the remainder. Both Dollinger [7] and Hagenbach [8] prefer conduction anesthesia by circular infiltration proximal to the site of fracture. Fulton,[9] a British surgeon, reported five cases in 1921. The most recent writer on the subject is Frostell,[10] who, in 1925, advocated the use of the method without giving any details. The method is described by Baun and by Hertzler in their books on local anesthesia, and is mentioned by Allen.

Since 1924, I have used local anesthesia in the reduction of fractures. The method employed has been one of local infiltration at the site of the break. It is obvious that anesthesia can be induced by spinal injection for the lower extremity, or by nerve block of the brachial plexus in the upper extremity. The possible dangers of these procedures outweigh any advantage gained over the use of a general anesthetic. In lesions of the phalanges, nerve block of the digital nerves may be used.

METHOD

Procaine solution, from 0.5 to 1 per cent strength, with epinephrine, is used. When it is obvious that a large amount of the solution will be needed, as in the thigh, the lesser strength is chosen. The site of the injection is over the seat of the fracture. Every effort is made to select a spot where the skin appears normal, and to avoid injecting through or into plainly devitalized tissues. A needle of sufficient length to reach the bone is required. The solution is injected between the fragments and about them, as well as into the surrounding muscles. It may be possible at times to complete the infiltration through one puncture, the needle being moved about in the tissues and left in situ while the syringe is refilled. Where there is considerable overriding of the fragments, it may be necessary to inject separately over each bone end. When two bones are broken, as in the leg and the forearm, two separate punctures are needed; and two punctures were found to be convenient in Colles' fractures and in fractures of the femur. The amount of the solution used has varied from 20 to 150 cc.; the latter amount was used in a fracture of the femur in a muscular man. It will be noted in some cases that, when the needle point lies between the bone fragments, blood will rise in the syringe from the site of the fracture. The color is lighter than that which would be obtained if the needle were in a vein. Further differentiation can be made by inserting or withdrawing the needle a short distance; if it is a vein, the blood will cease to well up, but the amount extravasated about the site of a fracture is usually sufficient to continue rising in the syringe.

INDICATIONS

Whenever a local anesthetic is the choice for a major surgical procedure, its use would be indicated in the treatment of fractures. Under such a heading would come the aged, and the patient with a decompensated heart or with pulmonary or renal disease. As an example:

> A woman was referred to me because of an impacted Colles' fracture. She had been under treatment for many years for hypertension, and a general anesthetic was contraindicated. An attempt at her home to correct the deformity without any anesthetic was unsuccessful. The following day, after the injection of 30 cc. of 0.5 per cent procaine, the fracture was reduced without any pain.

The majority of the fractures of the upper extremity are ambulant cases; they make up part of an office or outpatient rather than a hospital practice. It is in this type of fracture that local anesthesia will find its greatest field of usefulness, even though a general anesthetic is not contraindicated. In the following case a third indication can be seen:

> A child, aged 8, admitted to the hospital with a fracture of the skull and of the femur, was in severe shock for twelve hours, and the fractured leg was treated with a temporary splint. The following day, after local infiltration with procaine, the fracture was painlessly handled, and the possible dangers of a general anesthetic were avoided.

A fourth indication will be found in the following report:

> A woman, aged 60, came to the outpatient department complaining of pain in the shoulder following a fall the previous day. All attempts at examination were resisted by the patient,

---

who cried out at the slightest touch. After the injection of 10 cc. of 1 per cent and 10 cc. of 0.5 per cent procaine in the region of the head of the humerus, a satisfactory examination was made. The patient had a fracture of the greater tuberosity.

A use of the procedure suggests itself, although I have not had occasion to employ it. A fracture could be anesthetized in the operating room, and the patient go a distance to the roentgen-ray department for reduction of the fracture under the fluoroscope. This would be preferable to the transportation of an unconscious patient or to the administration of a general anesthetic in the roentgen-ray department. The only occasion I have had to use local anesthesia in a dislocation was that of a muscular man seen in the accident ward of the hospital. The intern in charge had been unable to reduce a dislocated phalanx. I failed on my first attempt, but succeeded readily after blocking the digital nerves.

CONTRAINDICATIONS

The one true contraindication to the use of local injection at the site of fracture is a compound fracture. If it is badly compounded and soiled, local infiltration may well spread infection into the surrounding tissues. Even in cases which do not seem in need of operative intervention, infection may be present to show itself several days later. Until the use of local anesthesia is more common in the treatment of fractures, one would not care to have a suspicion arise that its use was a possible factor in the infection. Circular injections, well removed from the site of the lesion, could be used in this type of case. Objection may be raised to the local infiltration on the grounds that we are converting a simple into an open fracture and thus invite infection. With proper asepsis, I believe this objection is theoretical. I have not seen even the suggestion of any reaction from its use, and none has been reported by others in large series of cases. A second possible objection that may be raised is that proper muscular relaxation will not be obtained. I thought this was probably correct until I used the method in a young negro porter of powerful build, who had a fracture of the femur at the junction of the upper and the middle third. A reduction was readily carried out on a fracture table after the injection of 150 cc. of 0.5 per cent procaine. The only complaint of the patient was the pressure from the perineal bar. A third point which might be raised against the use of local anesthesia is the impracticability of using it in children. I have successfully used it in three children under 10 years of age, and feel that by gaining the confidence of the patient it can be used at any age. By freezing the skin, the first puncture can be made painless. This puncture and, at times, a feeling of tenseness of the tissues have been the only complaints.

Local anesthesia has been successfully used in the following thirteen cases: fracture of the shaft of the femur, 2; fracture of the shaft of the humerus, 1; fracture of the tuberosity of the humerus, 1; fracture of the clavicle, 1; fracture of both bones of the forearm, 1; fracture at the wrist, 3; old fracture of the carpus (refractured), 1; fracture of the tibia, 1; fracture of the tibia and fibula, 1, and dislocation of the phalanx, 1. This group, while not extensive, is fairly representative of the various types of fractures. A satisfactory anesthesia was obtained in every instance.

CONCLUSIONS

1. The induction of anesthesia in fractures by local infiltration is a practical procedure.
2. It is useful in patients in whom a general anesthetic is contraindicated, and is particularly recommended for the treatment of ambulant fractures.

A METHOD OF STRIPPING THE SEMINAL VESICLE

REPORT OF TWO HUNDRED CASES OF CHRONIC SEMINAL VESICULITIS

EDWARD S. POMEROY, M.D.
SALT LAKE CITY

Chronic seminal vesiculitis is characterized by a symptomatology that is somewhat underemphasized and often unrecognized.[1] For the sake of calling attention to the more important features, let us recall that there is very often pain in the lumbosacral region [2] or perineum, and down the legs or in the knees; the patient is often underweight, with sagging muscles and skin pallor, and has a constant sense of fatigue or tires easily. He has lowered vitality and mental depression. The rapidity with which the pain disappears with increase in weight back to normal, with which there occurs a good color return to the skin, and a general sense of well being, with increased vitality and subsidence of all other distressing symptoms after a few, from three to six, thorough massagings and strippings of the seminal vesicles, is remarkably striking.

Undoubtedly the seminal vesicle, which is a hollow organ, plays as important a rôle in harboring infection as the prostate,[3] if not more so; and, since it represents an important unit in the channel that conveys the very germinal cell of human life, this is all the more reason for keeping it free from pollution. Almost any one can reach up into the rectum and push on the readily felt prostate; but, unless one has a clear conception of the anatomic relationships of this region and the importance of the seminal vesicle in infections of the genital tract, one is apt to fail in getting a specimen of pus where plenty exists, to say nothing of the consequent failure to give relief by the expulsion of masses of pus therefrom that can be accomplished if the proper manipulation is employed in stripping them.

The seminal vesicles are reported to be from 4 to 5 cm. in length (Piersol); "sometimes much longer and relatively slender and at others short and broad, they vary greatly in size and in detail of arrangement of their component parts, and not infrequently are markedly asymmetrical." They are sacculated and tortuous, and while their position is relatively fixed they assume great variations of angulation from the midline of the rectum. As they are lateral and above the prostate, and since the average forefinger of a man reaches not far above the upper border of the prostate, and as the patient usually experiences much tenderness in this region, relaxing reluctantly, it is not surprising that it is often difficult to empty these organs efficaciously by maneuvers of the surgeon's finger in the patient's rectum.

METHOD OF STRIPPING

To examine properly and to strip a seminal vesicle the patient should be relaxed, and the urologist should be able to explore the male pelvis with his finger as thoroughly as the gynecologist explores that of the female. It can be done with a little anesthesia for the patient and with a willingness to push on the part of the searching fingers.

The method I have adopted is to cleanse the penis with tincture of green soap, wash the parts with mercuric chloride solution, wash out the urethra with boric acid solution, and then instill 10 cc. of sterile 1 per cent butyn through the urethra, up past the external sphincter into the prostatic urethra with an ordinary sterile urethral syringe. This is massaged well into this region by rubbing it along the urethra and perineum, and then a rectal suppository containing 2 grains (0.13 Gm.) of butyn is inserted into the rectum A few minutes are allowed to obtain good anesthesia, after which we find that the rectal muscles are usually well relaxed.

The patient is placed in the position most desired by the surgeon for massaging the glands (we prefer either the standing position with good flexion at the hips, or the knee-chest position on the examining table), and with the forefinger covered with a cot one finds that the finger can be pushed well up into the pelvis beyond the prostate; and, swinging over to one side, one usually has no difficulty in finding the seminal vesicle. Beginning as high as possible, the finger is brought down along this organ firmly with a rapid stroke, which is repeated in a series of rapid strokes with a milking motion for several seconds. Then, if any areas of induration are felt, a steady, firm continuous pressure downward is made on each of these for a few seconds. The same procedure is applied to the vesicle on the other side, and then the prostate is massaged in the customary manner. If there are any coagulated agglutinated masses of pus and detritus in these organs, they are brought down into the prostatic urethra where they lie, too heavy to pass through it until washed out by an irrigation, and are seen if collected in a sediment glass often in sufficient quantity to settle in several inches thickness at the bottom of the glass.

Following the stripping and massage, the deep urethra is instilled with mercurochrome-220 soluble, as suggested by Young.[4] From three to twelve of these treatments usually free these organs of the most important masses of pus, and only the usual seminal and prostatic fluids remain, which most often now unfortunately show an excess of leukocytes for a persistently long period.

These manipulations should be done with much care; and although some firm and considerable pressure is sometimes necessary to expel the infected material, it should be done with all precautions possible, and with a thorough knowledge of the anatomy of this region, with due respect to the sacral plexus of nerves, the body of the seminal vesicle itself and the wall of the rectum, to avoid injury to any of these or other adjacent structures.

In considering the 200 cases of chronic seminal vesiculitis in which treatment was done in this manner, we found that all the patients gave histories of gonorrheal infection of from four months to many years' standing, with "morning drops," recurrences of acute exacerbations of freely flowing pus from the urethra, local irritations, epididimytis, and the usual array of manifestations characteristic of this affection. Eighty-five per cent of the patients manifested symptoms of backache, loss of weight, lowered vitality and depression in varying degrees, and 15 per cent were practically free from all these symptoms except the "morning drop" or some local irritation. Under our management, in practically all cases the pus was reduced to a mere trace before cessation of treatment, most of them presenting great masses of pus at first in the massage secretions; in all the cases there was relief from distressing symptoms, and in most cases an increase in weight of from 5 to 25 pounds (2.3 to 11.3 Kg.) in from four weeks to twelve months. Ten per cent of the patients were freed from all traces of pus in from ten weeks to twelve months, and were discharged subject to periodic reexaminations. About half of these have reported over a probationary period of many months and were found to have remained clean. Eighty per cent voluntarily ceased to appear for treatment before complete disappearance of the last trace of pus, a few of these returning later at periods of from six months to a year again to resume treatment, some presenting a freshly acquired acute anterior urethritis either from an extraneous source or from their own deeper structures, but most of them precisely where they left off, with only a trace of pus on massaging. Ten per cent are still under treatment.

No patient has suffered any ill effects from a series of rather vigorous stripping of the seminal vesicles and massagings of the prostate gland, aside from minor aches along the vas deferens for a few hours afterward; in a few, slight bleeding from the rectum occurred and some experienced a degree of pain during the treatment in spite of the anesthesia. Twenty per cent suffered transient and unalarming dizziness or went into complete syncope with blanching of the skin and profuse sweating immediately after the massage, from which they promptly recovered. I believe that the reaction of syncope here is not psychic, and offer as possible explanations of its cause that it is either a sudden flooding of the system with toxins liberated by the massage, or that it is purely an autonomic nerve reflex receiving its stimulus in the sympathetic nerves of the stripped organ and manifesting itself in the activity of the vasoconstrictors of the brain and skin.

CONCLUSIONS

From a study of these cases, I feel that the importance of chronic seminal vesiculitis, and particularly in gonorrhea, has been underestimated; that the symptoms of this affection are underemphasized, as well as the readiness to which they respond with proper treatment; that with the help of even a mild anesthesia the parts become relaxed and treatment facilitated; that a quick, rapidly repeated milking motion applied to these vesicles is advantageous in emptying them; that careful strippings deliver the vesicles of masses of agglutinated pus, often hard and lumpy, which might otherwise never become dislodged, and that the phenomenon of syncope occurs in many cases immediately after a massage, particularly the initial one.

CHOLECYSTOGRAPHY: THE USE OF PHENOLTETRAIODOPHTHALEIN *

EVARTS A. GRAHAM, M.D.
WARREN H. COLE, M.D.; GLOVER H. COPHER, M.D.
AND
SHERWOOD MOORE, M.D.
ST. LOUIS

In previous publications we[1] stated that observations were being made to determine whether or not phenoltetraiodophthalein would prove to have superior advantages over tetraiodophenolphthalein for purposes of cholecystography. It will be recalled that these two substances are isomeric compounds differing from each other in the location of the iodine atoms in the molecule. Phenoltetraiodophthalein also is characterized by its ability to stain the serum sufficiently to make it of use in determinations of hepatic function, for which purpose it has the same possibilities as phenoltetrachlorphthalein.

We have now given the sodium salt of phenoltetraiodophthalein intravenously to fifty patients. For purposes of intravenous use in cholecystography it seems to possess very decided advantages over anything else hitherto employed. Satisfactory shadows of the gallbladder can be obtained with smaller doses than with the isomeric compound, tetraiodophenolphthalein. Its use, therefore, is followed by fewer and much less severe toxic reactions, although within the last year these have been negligible with the tetraiodophenolphthalein. The toxicity of this whole group of substances seems to be due chiefly to the phenolphthalein part of the molecule, as judged by the fact that toxic effects can be produced by injections of phenolphthalein alone which are apparently identical with those produced by the halogenated phenolphthaleins. As an average intravenous dose, we have used the phenoltetraiodophthalein in amounts of 0.04 Gm. per kilogram. We have used amounts up to 2.5 Gm. for adults. We have not found it necessary to exceed that amount in any case, although it is conceivable that unusually large persons might require larger doses than this. For the sake of convenience we ordinarily give it in one dose dissolved in 30 cc. of freshly distilled water. In this way it may be given easily with a syringe. But if larger dilutions are desired it may be given by the gravity method. In the fifty cases there were three instances of slight dizziness of no more than ten minutes' duration. In the other cases there was no reaction of any kind. The fact that it gives satisfactory results in relatively small doses makes it possible also to make the injection all at one time without the same fear of toxic reactions as is the case if the larger dose of tetraiodophenolphthalein is given at one time. Likewise the danger of thrombophlebitis is reduced, and we have had no instances of this in our series of fifty cases. A final advantage lies in the fact that this substance seems to be more rapidly excreted through the liver, and accordingly the time necessary for a cholecystographic examination can therefore be shortened. Excellent shadows of the gallbladder may usually be obtained in four hours after the injection of the phenoltetraiodophthalein. The interpretation of cholecystograms produced by phenoltetraiodophthalein is the same as we originally described for the halogenated phenolphthaleins.

We have had only indifferent success with this substance when administered orally. In our experience the method of intravenous injection continues to give a diagnostic accuracy of 97 per cent, as compared with an accuracy of only about 75 per cent with the method of oral administration.

The hope expressed previously that, since it colors the urine, it might be used for studying the renal function seems not to be borne out by later work, for the reason that only about 3 per cent of the dye is excreted in the urine even with normal conditions.

The decided advantages possessed by phenoltetraiodophthalein over tetraiodophenolphthalein for purposes of cholecystography have caused us to substitute the former for the latter in routine use in the Barnes Hospital.

Since sending this manuscript to press we have found still another substance which gives excellent cholecystograms. This is the sodium salt of tetraiodoisophenolphthalein. Preliminary experiments indicate a marked absence of toxic effects, but we have not yet used it sufficiently to know whether it possesses any advantages over phenoltetraiodophthalein.

EXPERIENCE WITH CHOLECYSTOGRAPHY IN CASES COMING TO OPERATION *

C. C. McCOY, M.D.
AND
R. S. GRAHAM, M.D.
CLEVELAND

Since the introduction of cholecystography by Graham and Cole of St. Louis, numerous articles have appeared paying tribute to it as a measure of great value in the diagnosis of gallbladder disease. There have been, however, relatively few reports of series of consecutive cases coming to operation in which the cholecystographic diagnoses have been correlated with the findings at the operating table and in the pathologic laboratory. On this account, it has seemed to us that it might be of some value to present these correlations for our patients who have been operated on, and to tabulate, so far as it seems feasible, the similar reports found in the literature.

It is perhaps advisable to preface the presentation of our own cases by a brief summary of the technic and point of view in interpretation that we have followed, although these have been copied in all essential features from the work of others. Our joint experience with the test began about six months ago, when sodium tetra-iodophenolphthalein was coming into general use. This salt has been employed exclusively. The technic has varied somewhat, but the routine has been to give 3.5 Gm. of the salt between 8 and 9 o'clock in the evening, well after the usual evening meal, and to make the initial roentgenologic examination on the following morning, approximately twelve hours later. These hours of administration and examination were chosen because they fitted best with other hospital work. The intravenous route for administering the dye was generally used because it has seemed the most accurate, and we have not been impressed by there being any particular inconvenience or hazard in it. Some of the patients were allowed a small amount of food in the morning before appearing for the first roentgen-ray examination; this seemed to have no appreciable effect on the practical worth of the test, although it was undoubtedly an unwise digression from the generally accepted procedure.

---

* From the Department of Roentgenology, Lakeside Hospital and Western Reserve University School of Medicine.

In viewing the roentgenograms, we have endeavored in each case to make one of three diagnoses; namely, cholelithiasis, a pathologic biliary tract, or a normal biliary tract. The chief criteria used to differentiate these have been: (1) the presence of shadows regarded as representing calculi, and (2) the degree of visualization of the gallbladder. A diagnosis of cholelithiasis has been made whenever the control films or the cholecystograms or both showed shadows of increased density that looked like calculi, and when in the cholecystograms a visualized gallbladder presented shadows of diminished density that had a similar resemblance. The fact that stones are frequently revealed in the latter fashion in gallbladders that seem otherwise to respond quite normally to the dye makes it unwarranted, in our opinion, to infer from this test alone that there is in such cases any other pathologic condition than the stones present; hence, the distinction has been made in the roentgenologic interpretation between cholelithiasis and a pathologic biliary tract. The diagnosis of pathologic biliary tract has been applied to those cases in which there was no visualization of the gallbladder and to those in which this visualization was indistinct; in several of these, calculi were found at operation, but neither the control roentgenograms nor the cholecystograms afforded any definite evidence of their existence. A clear cut visualization of the gallbladder by the dye has been regarded as implying a normal biliary tract. Since cholecystography should probably be considered as primarily a measure of gallbladder function, it is to be expected, as with any functional test, that there will be all degrees of response to it; and while such graduated variations undoubtedly occur, in our limited experience there have been practically no cases that seemed in the midzone between normal and pathologic so far as visualization was concerned; almost without exception, they have appeared definitely one or the other.

Table 1 shows the twenty-six cases that we have had in which the test was employed and operation performed; three cases in which oral administration alone was tried are not included, because faulty vehicles prevented the absorption of the dye, and therefore no diagnostic opinion could be expressed. The control films of the gallbladder region were taken ordinarily from twelve to thirty-six hours before the giving of the dye; a naught in this column signifies that nothing suggestive of stones or gallbladder was seen. Under cholecystograms, the demonstration of stones is indicated by a plus sign or number in the column headed stones. The findings on the films taken twelve hours after the administration of the dye are the only ones tabulated; in this column, a plus sign indicates good visualization of the gallbladder, and a naught indicates total lack of visualization; a faulty visualization is so stated. In listing the cholecystographic diagnoses, normal and pathologic are used instead of the expressions normal biliary tract and pathologic biliary tract. The surgical findings were taken from the operative notes, and the pathologic findings from the laboratory reports.

* In this column, plus signifies stone shadows present; 0, no stone shadows

† In this column, plus signifies normal visualization of gallbladder, 0, no gallbladder shadow seen

In five of these twenty-six cases, a diagnosis of cholelithiasis was made by cholecystography, and stones were found in each at operation. Of thirteen cases diagnosed as pathologic biliary tract, eleven showed gross evidence of disease, eight patients having stones, two presenting definite pictures of chronic cholecystitis, and one having what was presumed to be a carcinoma of the ampulla of Vater that was obstructing the common bile duct. In one case in which a laparotomy had already revealed an acute hepatitis and cholangeitis with a bacteria-laden bile, the test was performed two weeks after the operation, and although the status of the biliary apparatus at the time the examination was made is not known, it seems to us reasonable to suppose that there was a pathologic condition then present sufficient to support the impression of disease given by the cholecystograms. In only one case in which the diagnosis of pathologic biliary tract was made did the operation fail to disclose gross evidence of disease, and in this case, although the surgeon considered the gallbladder normal, it was removed and from microscopic examination was adjudged by the pathologist to be the seat of a "mild chronic cholecystitis." In the eight cases interpreted as normal by cholecystography, seven were considered so at operation and the gallbladders were not removed. It is possible that a pathologic examination would have yielded evidence of disease in some of these. The eighth case showed adhesions about the gallbladder; the surgeon, thinking it diseased, removed it, but inspection of its interior and microscopic examination of its walls supplied no evidence of abnormality.

In a few cases we have endeavored to obtain gallbladder shadows following the oral administration of bromides, as suggested by Sabatini and Milani,[1] but without success; rather dense shadows of the urinary bladder were, however, secured.

Thus, of these twenty-six cases in which operation was performed, the cholecystographic diagnosis failed of confirmation in only one, and in it the findings were somewhat equivocal. This gives a diagnostic accuracy of 96 per cent for the method as evaluated by surgical and pathologic examination.

Table 2 is an attempt to assemble the cases recorded in the literature in which the findings by cholecystography have been compared with the findings at operation. In arranging these cases under the headings chosen, some liberty has been exercised on our part and some mistakes have probably been made in doing so. Of the 212 cases examined with intravenous administration of the dye, the diagnoses made from the cholecystograms were substantiated at operation in 91 per cent; in the cases with oral administration, the confirmation was somewhat lower but was nevertheless more than 80 per cent. In the number regarded as errors there have been included some which were doubtfully so, and probably a few of the early cases with later technic and interpretation would not have been thus classed. Variations in different clinics have depended presumably in large measure on the differences in types of patients submitted to examination, and on difference in points of view of surgeons, roentgenologists and pathologists; thus, the results are scarcely comparable except in indicating a general agreement on the high diagnostic value of the method.

[1] Sabatini, G., and Milani, E.: Visibilite radiologique de la vesicule biliare apres administration "per os" de bromures alcalins, Presse méd. **33**: 1160 (Aug. 29) 1925.

SUMMARY

1. In twenty-six consecutive cases in which operation was done in this clinic, the cholecystographic diagnoses were confirmed at operation in 96 per cent.

2. In 212 cases collected from the literature, with intravenous administration of the dye, the cholecystographic diagnoses were confirmed in 91 per cent. In cases with oral administration of the dye, the confirmation was more than 80 per cent.

3. The accuracy of cholecystography in predicting gallbladder disease merits its wide use as a procedure in diagnosis.

THE PRECLINICAL STAGE OF HEART DISEASE *

S. CALVIN SMITH, M.D.
PHILADELPHIA

On first thought it may seem that an attempt to establish a preclinical stage of heart disease is a refinement in diagnosis attainable only by a select few. Such is not the case. Sufficient evidence has accumulated since the days when hearts were, for the most part, studied at the bedside to show that organic heart defect is usually the result of several successive phases of development, quite comparable to the germinating grain of corn that evolves the blade, the stalk and eventually the ripened ear. Chronic myocarditis—for which a more appropriate name would often be progressive heart muscle inefficiency—is generally the ultimate end-result of accumulated heart protests which, at their inception, we once were wont to wave aside with a gesture of inconsequence.

EARLY SYMPTOMS MORE CONSTANT THAN EARLY SIGNS

Heart protests, in the beginning, are nearly always subjective symptoms alone, and the symptoms need not at all be confined to the left chest. Physical findings at this stage may be expected to be absent. The heart is found either normal or else not sufficiently disturbed in function as yet to yield the familiar group of signs on which a diagnosis of heart disease can be classically constructed. When heart defects attain the coarse proportions of persistent and transmitted murmurs, profound heart enlargement, grossly irregular pulse, congestions, edema, anasarca and physical prostration—except in those comparatively rare cases in which an acute illness acutely involves the heart—there is little that can then be done for either heart or patient. Such signs as these announce the approaching end of life.

The aim in this age of conservation, the fundamental purpose of periodic health examinations, is to anticipate and, by the correction of underlying faults and defects, to avoid such cardiocirculatory catastrophes as "typical heart disease." This can be accomplished by the early recognition of early heart protests.

PRECLINICAL SYMPTOMS OF HEART AFFECTIONS

The preclinical stage of heart embarrassment can be reduced to five symptoms, of any one or more of which the patient will complain. These five symptoms include shortness of breath, heart hurry, chest oppression, chest pain and physical fatigue, all attendant on moderate or accustomed effort. The presenting of such symptoms warrants the most assiduous search, both of the heart and elsewhere throughout the body, for the cause of these early heart protests.

THE "ACUTE INDIGESTION" FALLACY

Patients frequently assert that the foregoing symptoms are relieved by belching, and that therefore the heart protests are due to "gas pressing on the heart." "Acute indigestion" is a favorite newspaper headline elaboration of the same idea, grasped to explain the sudden cardiac deaths of prominent men. "Indigestion" is the black beast of the cardiologist, and the most difficult of all obsessions of which to rid the patient, once he has evolved this satisfying concept. As medical men we know how unconsciously and with what ease one can eructate. The upper end of the stomach is not an air-tight structure to imprison gases that later by their accumulation forcibly explode. And even if the opening to the stomach by neuroses might contract, it would seem that distention of the gastric walls by gas would mechanically draw the distention apart.

So why permit this "gas pressure" delusion longer to encumber a patient's thoughts and lull him into a false sense of security? Surely it is more logical to assume that decomposition of food occurs because the heart is incapable of supplying the stomach with blood sufficient to elaborate digestive juices or motivate the stomach; or one might adopt the hypothesis that the heart is embarrassed reflexly by way of the pneumogastric nerve which supplies both stomach and heart. Whatever the underlying cause in a given case might be, it is a clinical fact that when a heart can be embarrassed by "gas pressure" there is usually something wrong with that heart.

PHYSICAL SIGNS OF THE PRECLINICAL HEART

There are physical signs that the physician may find within the heart itself, and others that are to be sought for elsewhere in the body, which may indicate a beginning heart affection. Among those to be found in the heart may first be mentioned the "extra beat" or intermittent pulse which, however long established in the apparently healthy, is always abnormal and always a sign of heart protest. Second in importance is some degree of heart enlargement in the transverse heart diameters, detected by percussion and determined by the roentgen ray. The sounds in such a heart may be sharp and clear before the exercise test, but muffled and indefinite following effort; or the reverse of this situation may prevail, especially in patients who at some time have been engaged in strenuous competitive athletics. The rate response of the heart to exercise, which usually in the normal returns within two minutes to the preexercise rate when sitting, may continue for a longer time to remain elevated from twenty to forty beats; or an affected heart may actually slow down in rate under an exercise test and not attain the previous rate until several minutes have elapsed.

Any one of these early heart signs—intermittent pulse, heart enlargement, auscultatory phenomena, rate response—is of sufficient importance to warrant some degree of heart care and intensive heart study.

EARLY PHYSICAL FINDINGS OUTSIDE THE HEART

First among the physical findings that may be encountered outside the heart is the occurrence of râles at the base of the left lung posteriorly, often an early and always a valuable sign of heart impairment unless otherwise explained. Anemia, thyroid enlargement, vasomotor disturbances, dizziness on sudden change of posture, all call for heart suspicion. Either overweight or malnutrition may tax the heart. Emotional upsets in the temperamentally placid or continued high tension in persons of neurotic tendencies may eventually establish

---

* Prepared for the Committee on Periodic Health Examinations.

heart imbalance with resultant circulatory inefficiency. The "toxins of fatigue," from too intensive physical application or mental concentration, can certainly harass the heart.

APPLYING THE REMEDIES

When a physician conducting a periodic health examination has found symptoms or signs indicative of early heart involvement, he naturally next addresses his attention to the correction or removal of underlying causes. The search for such factors begins with evaluating the patient's previous history. It may be that a heart has been affected earlier in life by one of those diseases which is known to throw a heavy load on it, and that heart is no longer sufficient to support the circulation in the patient's present occupation, circumstances or at his present age. Habits may be faulty and need correction. The patient may require guidance in personal hygiene—in matters of diet, weight, exercise, rest or diversion. Some hidden constitutional disease may need to be sought and corrected to relieve the heart embarrassment.

In any and every instance of heart protest, regardless of other likely causative factors, the tonsils should be required to establish their right of occupancy in the throat, and this applies regardless of the age of the potential heart patient. Each tooth should prove its innocence by roentgen-ray study and by the clinical examination of a not too conservative dentist who is familiar with the relation existing between dental defects and organic involvement elsewhere in the body. Drugs that act directly on the heart are rarely if ever required in the preclinical stages of heart affections.

Through such inspections, considerations and methods as those here outlined, a physician may logically expect to appraise the preclinical stage of heart disease.

DIABETIC COMA AND INSULIN

LEWIS FOX FRISSELL, M.D.
AND
JOSEPH HAJEK, M.D.
NEW YORK

Before Banting's discovery of insulin, diabetic coma was a serious condition to treat, both in the wards of the hospital and in private practice. Since the advent of insulin, the mortality has diminished to such an extent and with such rapidity that death caused by diabetic coma now appears as unnecessary.

In this article, an attempt is being made to show the difference in mortality before the discovery of insulin and since that time, with especial reference to diabetic coma. For this purpose, all diabetic patients admitted to the wards of St. Luke's Hospital during a period of four years are made subjects of study; they are divided into two groups, group 1 covering the preinsulin and group 2 the postinsulin years.

It will be noted that the first, or preinsulin, group covers the two years just prior to the discovery of insulin, and the second group covers the first two years after its discovery, beginning, however, with 1923; 1922 is intentionally omitted as a year in which the use of insulin was restricted by the supply.

GROUP 1

During the period 1920-1921, 113 patients with diabetes were admitted to St. Luke's Hospital—fifty males and sixty-three females. The medical division cared for 101 patients, and the surgical division treated twelve.

The medical service recorded eighteen deaths among the 101 patients treated, or a total mortality of 18 per cent. Diabetic coma was responsible for twelve of the eighteen deaths. In the remaining six cases, the immediate cause of death was due to other diseases than diabetes, leaving a mortality of 12 per cent due directly to diabetic coma.

Of the twelve patients treated in the surgical division, four died, a 33 per cent mortality, though none died in diabetic coma. Table 1 shows the mortality and the causes of death.

TABLE 1.—*Mortality in One Hundred and Thirteen Cases (Group 1, Fifty Males, Sixty-Three Females) of Diabetes in St. Luke's Hospital in 1920-1921*

Cases	Deaths	Mortality, per Cent	Cause of Death
Medical Service			
101	18	18	Diabetic coma, 12; lobar pneumonia, 1; cardiac failure, 2; renal disease with hypertension and cerebral hemorrhage, 2; cardiorenal disease, 1
Mortality due to diabetic coma, 12 per cent			
Surgical Service			
12	4	33	Gangrene of right foot, pneumonia and acidosis, 1; otitis media, sinus thrombosis and acidosis, 1; gangrene of the leg and septicemia, 1; multiple abscesses with septicemia, 1

GROUP 2

During 1923-1924, 163 patients with diabetes were treated at the hospital; seventy-eight of them were males and eighty-five females. In the medical service, of the 134 treated, thirteen died, giving a total mortality of 9.7 per cent. Only one among these died in coma, a mortality from coma of 0.7 per cent.

The surgical service cared for twenty-nine cases, resulting in seven deaths, none being due to coma. In table 2, the causes of the thirteen deaths are given.

TABLE 2.—*Mortality in One Hundred and Sixty-Three Cases (Group 2, Seventy-Eight Males, Eighty-Five Females) Treated During 1923-1924*

Cases	Deaths	Mortality, per Cent	Cause of Death
Medical Service			
134	13	9.7	Diabetic coma, 1; pneumonia, 3; empyema, 1; cardiorenal disease, 2; carcinoma of the colon, 1; leukemia, 1; chronic endocarditis, 1; acute mastoiditis, 1; gangrene of foot with gas bacillus infection, 1; carbuncle with septicemia, 1
Mortality due to diabetic coma, 0.7 per cent			
Surgical Service			
29	7	24.4	Carcinoma of the sigmoid, 1; acute appendicitis with abscess, 1; cardiorenal disease, 1; uremia with gangrene of foot, 1; gangrene of foot and septicemia, 1; carbuncle with septicemia, 1; cellulitis with septicemia, 1

SUMMARY

In comparing the mortality of the two groups, the preinsulin period with the postinsulin, we find that:

1. The mortality due to diabetic coma dropped from 12 per cent to 0.7 per cent.
2. The general mortality diminished about 9 per cent.
3. Infection is the most frequent cause of death in patients suffering from diabetes, and as ordinary infections are not influenced by the use of insulin, which must often be used in much larger doses, emphasis is to be put on the prevention of infection rather than its cure.

791 Park Avenue—260 West Seventy-Second Street.

INTRAGASTRIC RADIUM TREATMENT OF CARCINOMA OF THE STOMACH *

THOMAS O. MENEES, M.D.
GRAND RAPIDS, MICH.

The frequency and low operability of cancer of the stomach make improved methods of irradiation desirable. The application of radium immediately to the growth has definite advantages over external roentgen-ray therapy alone.

Pinch[1] has applied radium to the interior of the carcinomatous stomach by having the patient swallow a radium tube on a string. The position is observed by the roentgenoscope, and the radium may be moved by pulling on the string. From this, he has obtained definite palliative results, in slowing the rate of growth, checking hemorrhage, and relieving pain.

With radium applied in this way, the surface of the tumor bears the brunt of the exposure. Adjacent sensitive organs are protected by the rapid decrease in the intensity of irradiation, with distance. This permits heavy caustic irradiation, sufficient to influence highly resistant scirrhous carcinomas and adenocarcinomas. Roentgen-ray treatment could not be carried to this intensity because of the injury to other viscera in close relation to the stomach.

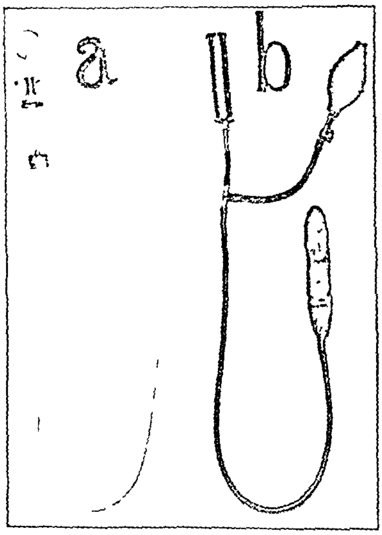

Fig. 1.—Intragastric radium applicator. In use, *a* is inserted in *b*; this permits movement of the radium in the distended stomach, without loss of the air, necessary to visualize tube and neoplasm, under the roentgenoscope.

By this method, the exact relation of the radium to the stomach wall is not determined, and uninvolved mucosa may receive excessive exposure. Also, there is little control over the position of the radium. Without accurate localization and control, a thorough irradiation of the surface of the tumor cannot be carried out.

For accurate placing of the radium, both tube and tumor must be visualized. A radium tube in the stomach is readily visible under the roentgenoscope, but the tumor is invisible without a contrast medium. With the usual contrast medium, barium sulphate, the tube is lost in the barium shadow. This leads to the use of air, as it will contrast both. The air must be confined to keep it under control and prevent it from rising to the highest point of the stomach.

To meet these requirements, a rubber balloon was cemented to a small rubber tube.[2] The radium on a flexible spirally wound wire was placed inside this. The bulb of a sphygmomanometer was attached to the other end of the tube.

This applicator, when passed into the stomach and distended, gave a clear outline of the radium tube and the carcinomatous filling defect. It was unsatisfactory, because the radium could not be moved without loss of the air in the bag. To overcome this difficulty, the spiral wire carrying the radium is attached to the piston of a syringe (fig. 1). The free end of the rubber tube is drawn over the tip of the syringe to form an air-tight seal. The bulb is attached by a T-connection. Any movement of the piston of the syringe is transmitted to the radium through the spiral wire, and it can be pushed ahead or pulled back without loss of air.

The applicator is passed as a stomach tube into the portion of the stomach involved. It is distended to outline any irregularities of the tumor, and the radium is adjusted to the level of the growth by movement with the syringe (fig. 2). Gravity is of help in bringing the radium in closer contact with growths involving only one curvature, and the patient's position is changed to obtain this. An arrangement should be made by which the patient can be roentgenoscoped at right angles without change of position, as it is frequently important to determine the position of the radium in three dimensions, without moving the patient and displacing the radium.

The radium is used lightly filtered (0.5 mm. of silver) to obtain the greatest surface effect with the least general irradiation, and to minimize the time of application. The treatment is divided into short sessions of from one to three hours daily and continued until [illegible] the accessible surface of the tumor has been [illegible]. Usually 50 mg. is used. More would shorten [illegible] time of treatment but would stiffen the end of the applicator and make it difficult to pass into narrow or [illegible] lumina. In some cases a moderate amount of high voltage roentgen-ray therapy has been given also. This must necessarily be limited, because of the frequent roentgenoscopic examinations. The tube is small, and after passing, gives the patient little discomfort. A reasonable distention of the bag gives no sensation.

The radium cannot be satisfactorily placed in all cases by this method. Where the lumen is much narrowed or tortuous, it may be impossible. In growths limited to one curvature, occasionally the outline of the growth is difficult to obtain, and accurate placing impossible. Then, only small dosage would be permissible. In small tumors limited to the pylorus, it is difficult to place the radium accurately.

The microscopic structure of tumors has been sufficiently correlated with their response to irradiation to enable us to predict the effect on a given tumor, and the quantity necessary to affect it.[3] Adenocarcinomas and scirrhous growths, which constitute the majority of gastric cancers, demand heavy caustic irradiation to influence them. In these, the danger of perforation would not permit heavy dosage sufficient to destroy the full thickness of the tumor. So palliation is all that can be hoped for, with some surface destruction and possible fibrosis of the deeper portions. The more cellular tumors, as medullary and diffuse carcinoma, are quite sensitive to irradiation. One case probably belonging to this class has undergone a complete clinical retrogression, with disappearance of the filling defect (fig. 3). There has been no recurrence of symptoms in the two years since last intragastric treatment. Parham[4] considers colloid carcinoma as rather sensitive to irradiation, but none has been treated by this method. Naturally, metastases would not be influenced by this method.

---

* From the Blodgett Memorial Hospital.

[1] Pinch, A. E. H.: A Report of the Work Carried Out at the Radium Institute, London, from Jan. 1, 1922, to Dec. 31, 1922, Radium **2**: 56-58 (April) 1923.

[2] Menees, T. O.: Intragastric Radium Application, Am. J. Roentgenol. **11**: 561-562 (June) 1924.

[3] Ewing, J.: Radium Report of the Memorial Hospital (Second Series), New York, Paul B. Hoeber, Inc., 1924, p. 247.

As the majority of gastric cancers are relatively insensitive to irradiation, this method is practically only palliative. It is of value in slowing the rate of growth and relieving pain and hemorrhage. Probably, the greatest value is in opening up the narrow portions of the stomach by destruction of the surface of the tumor, and preventing an obstruction with its violent train of symptoms. There is also an increased fibrosis of the deeper portions of the tumor with restraint of growth and obliteration of blood vessels. Along these lines, much can be done to prolong and make more comfortable the life of the patient and allow death to occur from other complications, rather than as a result of hemorrhage or starvation from a complete obstruction.

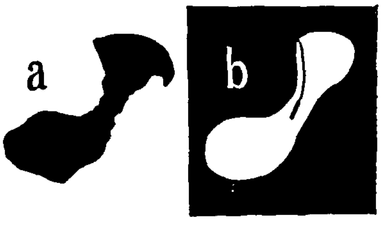

Fig. 2.—*a*, tracing of roentgenogram of barium-filled stomach, showing an extensive annular carcinoma of pars media; *b*, tracing of same stomach as *a*, with the carcinomatous filling defect outlined by the air-inflated bag of the applicator. The smaller irregularities of the tumor surface are lost, but the general contour of the involved portion of the stomach is clearly defined. The radium tube, which would be lost in barium, is sharply contrasted by air.

As it is practically palliative, the method is no competitor of surgery, but rather a complement. The pyloric growths accessible to surgery are the most difficult to apply radium to accurately. With the less accessible cardiac growths, it is much easier to place radium.

The dangers are probably small if proper care and gentleness are used in placing the radium. Perforation and hemorrhage would be the most serious complications. Perforation can be guarded against by not allowing the radium to come in contact with uninvolved portions of the stomach wall. Where involved, the stomach is thickened, and by using lightly filtered radium, the destructive effect is confined to the superficial portions of the tumor, and the possibility of perforation negligible. Hemorrhage from introduction of the radium is likely only in highly cellular growths with many poorly developed blood vessels. This hazard must be taken as these tumors are frequently highly sensitive to irradiation, and the tendency to hemorrhage is decreased by the obliterating endarteritis of the radium reaction.

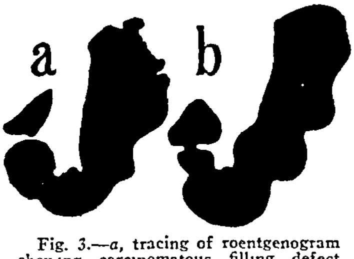

Fig. 3.—*a*, tracing of roentgenogram showing carcinomatous filling defect in fundus; *b*, tracing of same stomach as *a*, showing disappearance of the filling defect following intragastric radium treatment.

SUMMARY

1. By the method of intragastric application of radium described, a greater dosage can be applied to the surface of a gastric carcinoma with less general irradiation of the upper abdomen. This can be pushed to a caustic effect with superficial necrosis.
2. From this increased irradiation greater palliative effects can be obtained in slowing the rate of growth, checking hemorrhage, relieving pain, and preventing obstruction by destroying the surface of the tumor in narrow portions of the stomach.
3. The method is practically only palliative, and complete retrogression is only to be expected in highly cellular anaplastic growths which are not too extensive.
4. There is little danger in the method.

Clinical Notes, Suggestions, and New Instruments

CONGENITAL VARICOSITY OF THE ANGULAR VEIN

Ellis M Schwartz, M.D, New York
Associate Attending Physician, Ear, Nose and Throat Department, Peoples Hospital; Assistant, Ear, Nose and Throat Department, University and Bellevue Medical College Clinic

J. G., a boy, aged 20, came to me complaining of a small mass over the left nasal bone, which had been present for the last thirteen years. For the last two years it had been getting larger, until at the time I saw him, it was the size of a hazelnut. He came for medical help because of cosmetic reasons. The patient did not remember the mass appearing after a blow, but stated that it may have been there from childhood, and remembered seeing it first about thirteen years previously. On careful questioning, he said that when the mass first appeared, as far as he could remember, a doctor told him that by lancing the mass it would disappear and the trouble would clear up. It was probably then mistaken for a cyst. Fortunately resort to this treatment was not made. Six years previously, a simple mastoidectomy had been performed on the same side, but this was done years after the mass was noticed and had no bearing on the case at all.

The slightly bluish mass was situated over the left nasal bone, inside the inner canthus of the left eye, and was the size of a hazelnut. It was soft, and could be made to disappear on pressure. The nasal bone seemed to be eroded by the pressure of the mass. Believing it to be of venous character, I did the various tests, according to the anatomy of the venous system of the face, so as to show whether interference with the return flow of venous blood would have any effect on its size.

It is proper at this moment to review the anatomy of the facial vein.[1]

The frontal vein descends over the forehead on the side of the median line, lying beneath the skin, and terminates at the inner angle of the orbit by uniting with the supra-orbital vein to form the angular.

The supra-orbital is a relatively large trunk which runs transversely above the superior margin of the orbit. It arises at the external angle of the orbit, passes inward beneath the *orbicularis palpebrarum*, pierces the muscle at the inner angle of the orbit, and unites with the frontal vein to form the angular.

The facial vein is formed by the frontal and supra-orbital veins at the inner extremity of the eyebrow. It passes around the inner border of the orbit, then obliquely downward and backward across the face, over the ramus of the mandible in front of the angle, thence across the submaxillary and superior carotid triangles, to open into the internal jugular at the level of the hyoid bone. The portion of the vein from its formation to the lower border of the orbit is the angular vein, and branches arise from this which pass into the orbit to communicate with the ophthalmic vein Below the ramus of the jaw, it receives a large communicating branch from the external jugular, and the portion between this communication and the internal jugular is the common facial vein.

---

[4] Parham, D.: Colloid Carcinoma, Am. Surg. 77: 103-104 (Jan.) 1923.

[1] Piersol: Human Anatomy.

The facial and angular veins are destitute of valves, or have valves insufficient to prevent the flow of blood in an inverse direction—from the facial and angular veins into the ophthalmic. The two most important communications with the cavernous sinus are through the ophthalmic vein Much of the superficial blood of the face passes inward to the brain case and the interior of the facial region while the remaining blood flows downward to join the jugular veins.

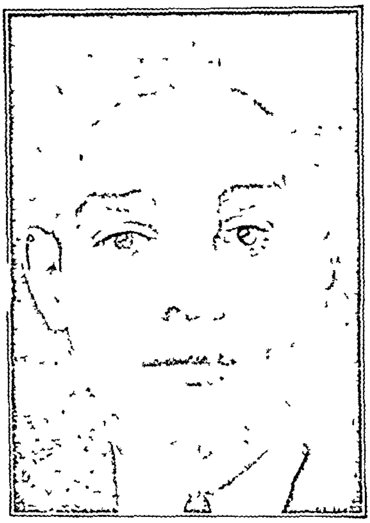

Fig 1—Effect on the size of the mass by the wearing of a very tight collar which demonstrates the interference with the return flow of venous blood by the collar and therefore the enlargement of the varicosity

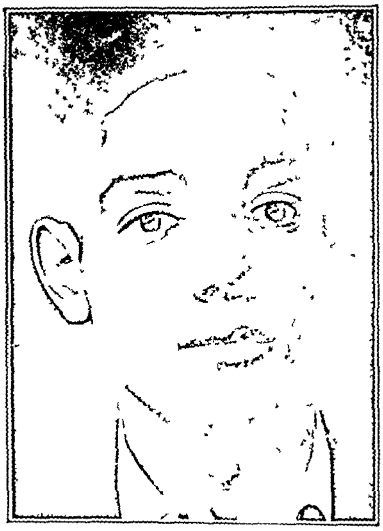

Fig 2—With the collar removed, the mass has entirely disappeared or is very slightly perceptible

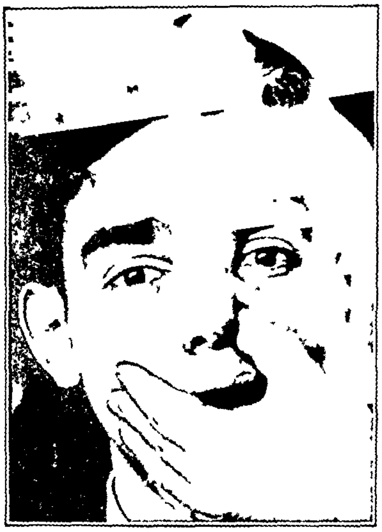

Fig 3—With the collar removed, pressure on the angular vein causes the reappearance of the mass.

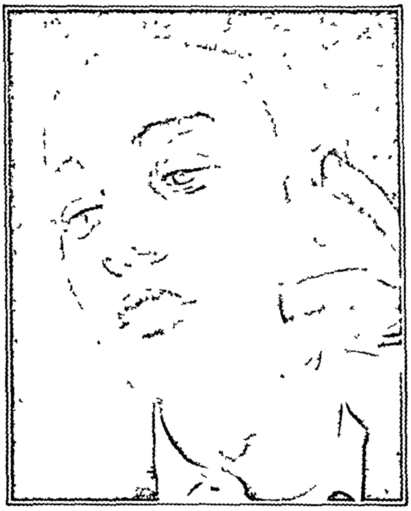

Fig 4—With the collar removed, pressure on the facial vein causes the reappearance of the mass

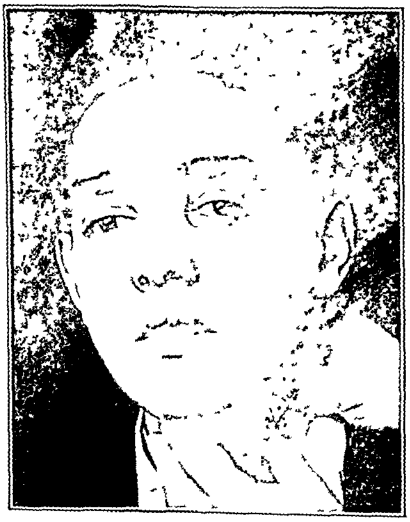

Fig 5—With the collar removed, pressure on the deep facial vein and the internal jugular vein causes the reappearance of the mass

The facial vein is less flaccid than most superficial veins. Because of these facts, I would emphasize the point which, although it has no direct bearing on this case, cannot be overlooked in the discussion of these anatomic relations, and that is, the ease with which septic infections of the face or forehead may spread by way of the ophthalmic vein or pterygoid plexus to the cavernous sinus, resulting in thrombosis or meningitis.

The superior ophthalmic vein will have a bearing on the eye findings in this case. It is sufficient to mention its tributaries, which are the anterior and posterior ethmoidal veins, the lacrimal vein, the muscular veins, the two superior venae vorticosae, the anterior and posterior ciliary venae and the venae centralis retinae.

When the patient's collar was tightened, the mass became larger, removal of the collar caused the mass to become smaller and barely noticeable. In order to show the effect of pressure on the veins by means of the finger, I had the patient remove the collar Then I compressed the veins at various points at which the return flow was interfered with. Pressure on the angular, facial, common facial and internal jugular veins increased the size of the mass. Removal of the pressure, thus removing the obstruction to the return flow, each time made the mass disappear.

Examination of the eyes showed corresponding changes in the veins of the eye on the side similar to that of the mass. The eyes were examined by Dr Martin Cohen, to whom I referred the patient with the belief that an interesting condition might be discovered, because of the anatomic communication between the angular and the ophthalmic veins.

With the patient's collar off, examination of the left eye showed the disk of normal appearance. The veins and arteries were normal. There were expansile pulsations on the physiologic cup. The right eye was normal.

With the collar tightened, examination of the left eye showed the conjunctival veins at the outer quadrant more injected than in the right eye After three minutes, the vein over the physiologic cup was getting larger than in the remaining portion of the retina, the pulsations were more evident. The superior and inferior retina veins were more engorged. There was no change in the course of the vessels and in the arteries. The cornea of the same eye, examined by the slit lamp, showed pulsations of the eyeball. In the right eye vascularization was normal. By the slit lamp method, the oscillatory movement was normal, and there were no pulsations visible. Physical examination by the internist revealed nothing of unusual interest, excepting a slight pulsation of the subclavian arteries. The systolic blood pressure was 136; diastolic, 86. Clinical examination of the blood revealed: nonprotein nitrogenous constituents, in milligrams per hundred cubic centimeters: uric acid 4.5; urea nitrogen, 12; miscellaneous constituents: sugar 0.097; chlorides, as sodium chloride, 0.492. To rule out congenital cardiac and vascular anomalies, the roentgen ray was employed, which showed the heart proportionately small and inclined to the dropped type, which, however, was more or less suited to the stature of the patient. There was no gross abnormality in the proportional dimensions or contour, excepting moderate hilum thickening. There was no evidence of gross pathologic change in either pulmonic field, excepting perhaps a hypervascularization a shade more noticeable in the upper lobes.

The Wassermann reaction was negative.

THE PURPOSES OF PRESENTING THE CASE

1. Since the history dates back thirteen years, I believe the condition may be regarded as congenital, as before that time it may have been so small as to attract no attention.
2. *The case presents an unusual location for varicosities.*
3. This type of mass should be differentiated from a cyst in that area or from a tear sac involvement. The consistency of the mass and its disappearance on pressure ruled out a cyst. There being no history of tearing of the eye and the mass being too high up ruled out dacryocystitis.
4. It is also important to differentiate this mass from a meningocele, because of the same location.

TREATMENT

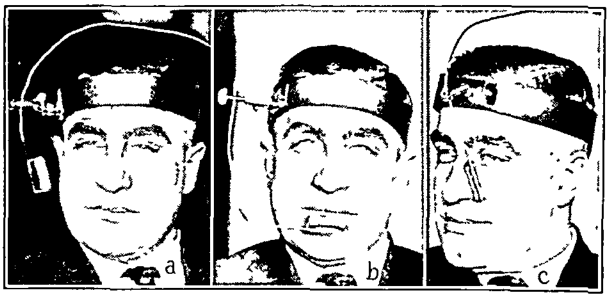
It is very essential for the patient to wear a loose collar, so as to remove any impediment to the return flow.

Until this day the patient has refused operation, but when he submits to the operation it will be necessary to ligate the supra-orbital and the frontal veins above the mass and the angular vein below the mass; the results should be good because of the sufficient collateral circulation in this area.

RADIUM APPLICATOR FOR TREATMENT OF LESIONS ABOUT THE HEAD, FACE AND NECK

William H. Kennedy, M.D., Indianapolis

Great difficulty has been experienced with methods of applying radium to the face, head and neck. This applicator, while very simple in construction, is adjustable to any angle by bending the copper wire, and when once adjusted remains in perfect contact with the lesion, allowing the patient to move his head in any direction.



Applicator in position (*a*) at distance; (*b*) for treating lip; (*c*) for treating nose

Another important consideration is distance without the use of blocks or gauze. This method eliminates the handling of radium, as it can be placed in the rubber tube with forceps and removed in the same manner.

It consists of a leather head-band, copper wire and universal ball joint made to be used with one-fourth inch rubber tubing, in which the radium is placed.

The applicator is manufactured by the Akron Surgical Instrument Company, Indianapolis.

A NEW URETERAL STONE EXTRACTOR AND DILATOR

Wilford A. Councill, M.D., Baltimore

In an effort to overcome the uncertainties of our present methods of treatment for ureteral calculi—waiting for the stone to pass spontaneously, ureteral dilatations and injections of oil, with the ever present possibility of permanent injury to the kidney, and perhaps final surgical intervention—I have devised an instrument which has been used successfully in a number of cases. This instrument gradually dilates and protects the ureteral wall while the stone is being extracted, thus minimizing trauma and reaction.

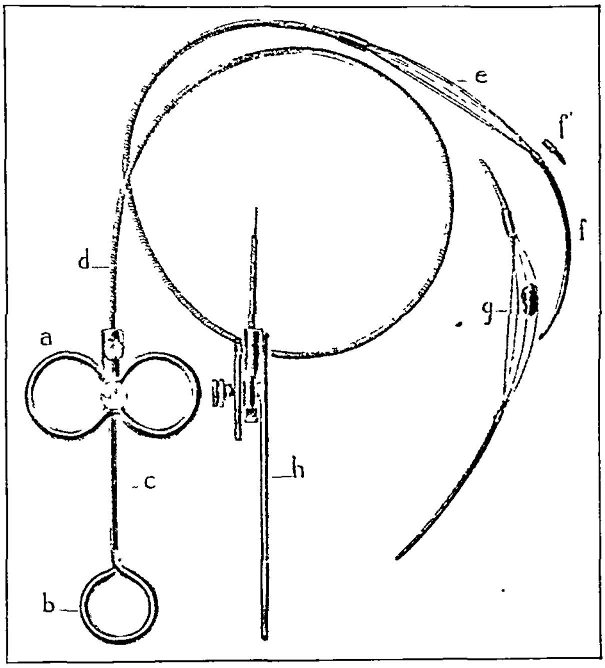


Fig. 1.—*a*, movable handle; *b*, ring for thumb; *c*, groove in shaft for the movement of *a*, *d*, spiral sheath; *e*, wires closed; *f*, filiform tip; f^1, metallic tip

Figure 1 shows a flexible instrument consisting of five principal parts: a movable handle, *a*, connected to an inner or central wire, *g*, and with thumb in *b*, slides in a groove, *c*, opening the mesh of wires for reception of the stone; *d* is a spiral sheath through which the central or control wire connects with the filiform tip, *f;* tension made on *a* causes the mesh, *c*, to open; the central wire, *g*, becoming an external wire, serves to hold the stone in place when tension is removed from *a*.

Preliminary to the extraction, a roentgenogram is taken to show the position and size of the stone, and a pyelogram is made to determine the size and condition of the ureteral tract. If strictures are encountered, they must be dilated before one proceeds further. When the ureteral tract has been dilated sufficiently, as confirmed by a second pyelogram, the extraction of the stone by the instrument may follow.

The patient is given morphine, ¼ grain (16 mg.), and scopolamine, 1/100 grain (0.6 mg.). An operating cystoscope is passed and the ureter in question catheterized. Procaine, 4 per cent, is injected into the ureter and allowed to remain for ten minutes. With the catheter still in place, olive oil is injected *until there is a fulness felt in the kidney region.* The catheter is withdrawn and the extractor passed up to the desired point (Fig. 2 *a*). A second roentgenogram is taken to show the relation of the extractor to the stone. When this is correct the mesh is opened (Fig. 2 *b*) thereby forcing the stone into the wires (Fig. 2 *c*). When the stone is brought down to the bladder, the handles of the instrument are removed and the cystoscope is withdrawn. The extractor is taken out through the urethra with the stone intact.

When the stone can be seen the fluoroscope is ideal, as each step can be followed from the introduction of the instrument to the extraction of the stone.

REPORT OF CASES

Eighteen stones have been removed from different locations in the ureteral tract, varying in size from a grain of wheat to that of a bean. Following are brief descriptions of three cases in the series:

Case 1.—J. K., tailor, aged 43, whose general condition was good, had been troubled with ureteral calculi for six months. He complained of a dull aching pain in the right kidney region associated with a slight frequency and some hematuria. A roentgenogram revealed a shadow about 4 cm. from the ureteral orifice A pyelogram showed a dilatation above the stone but no abnormalities below. Both ureters were catheterized and kidney function tests were made. Urine obtained from the left side was normal and the output of phenolsulphonphthalein, 30 per cent. The urine from the right side was cloudy and contained many pus and red blood cells, the phenolsulphonphthalein output being 10 per cent. An extractor was passed and a stone about the size of a pea was removed. Beyond a slight discomfort at the time of extraction, the patient had no ill effects and went to work the next day.

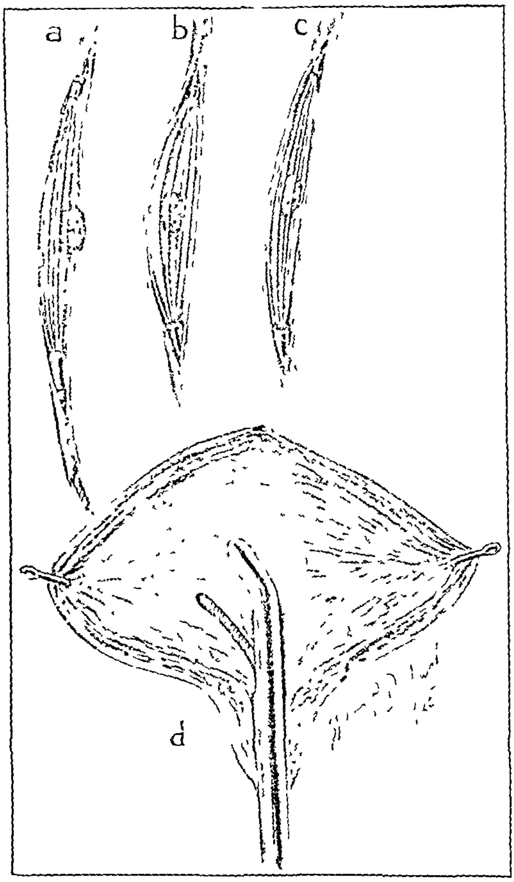

Fig. 2.—*d*, interior of bladder; cystoscope and stone extractor in ureter; *a*, wires at correct position; *b*, wires opened with stone enmeshed; *c*, stone extractor with stone enmeshed about to be withdrawn, showing how wires protect the lumen of the ureter.

Case 2.—H. M., a farmer, aged 47, whose general condition was good, had had intermittent attacks of renal colic for two years. He complained of pain in the left lumbar region associated with some frequency of urination and a marked hematuria. A roentgenogram revealed a shadow 2 inches (5 cm.) above the pelvic brim. The ureters were catheterized and specimens collected. The urine from the left side was cloudy and contained much pus; that from the right side was normal. Functional tests of phenolsulphonphthalein given intravenously showed: on the right side, appearance time three minutes; output, 30 per cent in half an hour; on the left side, appearance time, five minutes; output, 15 per cent. A pyelogram showed a dilated ureter and kidney pelvis above the stone; below, the ureter was small and constricted. After several ureteral dilations, the extractor was passed and a stone the size of a bean was removed. The patient returned in one week for further treatment. All symptoms cleared up. In this case an operation in all probability would have been necessary.

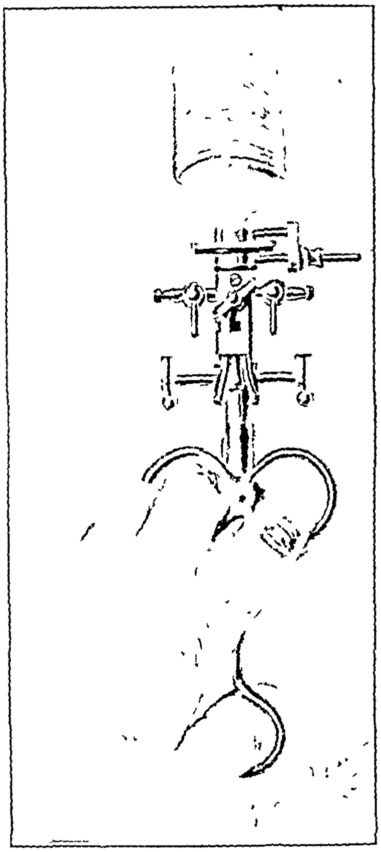

Fig 3.—Instrument introduced through cystoscope; method of opening wires either to dilate the ureter or use as a stone extractor.

Case 3.—H. T., an engineer, aged 30, whose general condition was good, entered the hospital complaining of pain in the left side associated with frequency of urination, urgency and hematuria. A roentgenogram showed a shadow about the size of a bean just below the pelvic brim. The cystoscopic examination was negative except for blood coming from the left ureter, which in turn was catheterized. As the catheter was passed, obstruction was met at the shadow, as shown in a roentgenogram and confirmed by a pyelogram. The patient left the hospital and later come to the office for treatment In a week's time a second roentgenogram was taken and showed the stone at the same position. After the ureter had been dilated sufficiently, a rough triangular stone was removed. Following the extraction, the patient complained of a slight discomfort for several days.

In another case the instrument served as a dilator and allowed the stone to pass of its own accord: A. M., a clerk, aged 50, primarily complained of pain in the back; he had had intermittent pain in the right loin associated with a slight hematuria for three months. A roentgenogram revealed a shadow just below the kidney pelvis, which was confirmed by a pyelogram. The usual routine cystoscopic technic followed and the extractor was passed. There was some difficulty in passing the instrument beside the stone, and instead of extracting the stone, it was pushed up into the kidney pelvis. The ureter was dilated and the patient told to return in two days for further treatment, but instead of returning at the time requested, he came in the next day, having passed the stone that night. This demonstrates that while there was a failure on extraction, the ureter was sufficiently dilated with the instrument to allow the passage of the stone.

SUMMARY

By this procedure, duration of pain, chance of injury to the kidney and possible surgical intervention are minimized, and even though the instrument was originally designed as a stone extractor, it has been used effectively as a dilator.

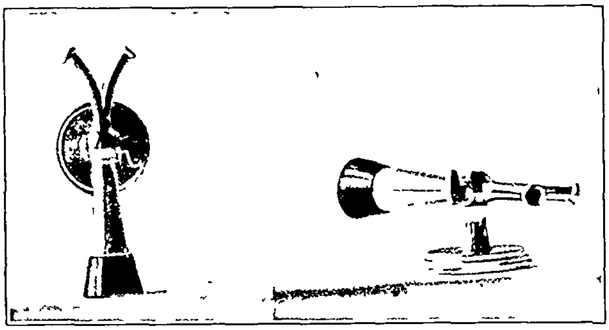
A NEW COMBINED STETHOSCOPE CHEST PIECE *

Howard B. Sprague, M.D., Boston

Because of the variable qualities of different cardiac murmurs, it has been evident for a considerable time that no single stethoscope chest piece is satisfactory in transmitting all the sounds produced in the heart. Ideally, a stethoscope that could be made to vary its optimal resonating qualities between wide limits in order to respond correctly to both high and low pitched sounds would be the most sensitive instrument to use. Practically, such instruments are cumbersome and complicated.

For clinical uses two forms of stethoscope chest piece have been found adequate in transmitting heart sounds and murmurs, except in the rare instances in which the naked ear is more satisfactory in responding to high pitched, blowing murmurs, such as those of aortic regurgitation. These two chest pieces are the bell type, which is most useful for low pitched murmurs, and the Bowles type, which registers high pitched murmurs more accurately.

The use of these two forms of stethoscope has been a routine procedure in the Cardiac Clinic of the Massachusetts General Hospital, and it is felt that no cardiac examination is complete unless advantage has been taken of the particular qualities of each chest piece. The bell stethoscope is capable of demonstrating rumbling diastolic murmurs of mitral stenosis which are inaudible with the Bowles type, and, conversely, the latter records the hissing or blowing murmurs of aortic regurgitation which cannot be heard with the bell.



Combined chest piece, showing position at left when bell is in use (front view) and position at right when Bowles section is in use.

The frequent changing from one chest piece to the other, often several times during the examination of a single patient in various positions, necessitated removing the aurals from the ears in order to avoid unpleasant noises, especially from striking the diaphragm of the Bowles. It also was inconvenient from the wearing out of the rubber tubes and the need for disposing of one chest piece when using the other.

The only alternative lay in the use of the Bloomfield or similar detachable connection. This we have found to be unsatisfactory for the reason that the connection tends to become loose, allowing the Bowles section to drop out or causing extraneous noises, and the combination does not do away with the necessity of disposing of the lower section while using the upper. I designed the instrument here described to remedy these difficulties. It is a combination of the Bowles and bell chest pieces in which each is in its customary position when in use. The illustration shows the mechanism, which consists merely in the connection of the receivers by a three-way valve. By simply turning this valve, one or the other chest piece is connected to the binaurals and the other is shut off. This precludes any loss of sound through the other chest piece and also prevents disturbance by extraneous noise.

Trial of this combination chest piece by Dr. Paul D. White and myself at the clinic has shown that its use makes the examination of cardiac patients much easier and more rapid.

The George P. Pilling & Son Company of Philadelphia have cooperated in designing the instrument.

Special Article

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(Continued from page 1837)

Medicated Enemas.—Medicated enemas for diacolonic action should, as previously stated, be given in the smallest bulk possible provided irritation is minimized by sufficient dilution. Starch water, being more efficient in lessening irritation, should be regularly employed as a diluent whenever such is required. Infusion of digitalis may be administered by rectum in tablespoonful doses, and even be made to carry a moderate dose of potassium acetate if desired. The following medicaments are generally well retained when given in the form of micro-enemas (30 cc.): tincture of opium, 1 cc.; chloral hydrate, from 1 to 2 Gm.; sodium salicylate, 2 Gm.; caffeine sodiobenzoate, 0.2 Gm. In prescribing enemas, the medicating ingredients are ordered from the apothecaries in pure form or in solution, which is then diluted, if necessary, with water, salt solution, or best starch water just before administration. Thus, in the treatment of infantile convulsions, we might prescribe chloral hydrate, 0.3 Gm. and sodium bromide, 0.6 Gm., in a teaspoonful of water, the dose to be diluted with 2 tablespoonfuls of starch water, and given by slow rectal injection.

Oil may be used as a vehicle for the diacolonic administration of oil-soluble volatile bodies. Thus, for colonic anesthesia, ether is employed in quantities of from 120 to 180 cc. with half the amount of olive oil, and the addition usually of 7.5 cc. of paraldehyde. The details of administration of these are given by Meyer and Robbins.[63] The interesting suggestion has been advanced by Goldbloom [64] to introduce, in the treatment of whooping cough, rectally 2 cc. of ether dissolved in 15 cc. of olive oil twice daily. He reports marked symptomatic improvement in a majority of cases in which he used it, especially in those cases that had well advanced into the paroxysmal stage.

For endocolonic action, in the treatment of catarrhal and ulcerative conditions of the large intestine, astringent enemas are of value. First among these deserves perhaps to be mentioned Cantani's tannic acid enteroclysis, which he used with success, especially in the premonitory stage of cholera, but which may also be employed in other inflammatory conditions of the colon. He injected slowly several times daily 2,000 cc. of 0.5 per cent tannic acid solution at about 104 F. The quantity of tannic acid may be varied from 0.25 to 1 per cent, and it may be most conveniently prescribed for the patient in form of the official glycerite of tannic acid (20 per cent), 25 cc. of which added to 1 liter of water yields a 0.5 per cent solution. The addition of acacia (5 per cent) or the use of starch water to lessen by colloidal demulcent action the irritation of the astringent is advisable. In chronic colitis with colonic tenderness and diarrhea, good results are obtained from enemas of silver nitrate, in 1:10,000 solution, gradually increased in strength from day to day to the point of tolerance (burning pain), which is usually reached with solutions of 1:1,000 or 1:2,000 strength. These astringent enemas are intended to be retained as long as possible.

---

* This is the twenty-fifth of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

[64] Goldbloom, Alton: The Use of Ether in Pertussis by Intramuscular and Rectal Injection, J. A. M. A. **85**: 1791 (Dec. 5) 1925.

Antiparasitic Enemas.—Quinine is quite unsuitable for absorption through the colon (diacolonic action), as has been shown by William Fletcher.[65] Weak solutions are too bulky to be retained, and the quinine is not absorbed sufficiently from them to enable one to rely on its action. Strong solutions, from 0.5 to 1 per cent, are so irritating that they are not, as a rule, retained longer than twenty minutes. The pain and tenesmus that follow the injection of strong solutions and the discharge of mucus and shreds of membrane, even after the use of weak solutions, are evidence of the poisonous action of quinine on the colonic mucosa. The absorption from 4 Gm. given by the rectal route was inferior to that from 0.15 Gm. given by mouth. For endocolonic action, on the other hand, quinine is useful. Thus, for the treatment of intestinal amebiasis, quinine sulphate or hydrochloride solution, from 1:2 000 to 1:1,000, in quantities of from 1 to 2 liters, is particularly recommended. The solution should enter slowly by gravity, through a long rectal tube passed as high as possible and should be retained as long as possible.

In cases in which such quinine treatment causes too much irritation, what might be called endocolonic osmotherapy, as suggested by Van der Togt,[66] might be resorted to. In experiments on means of destroying amebas by high osmotic tension in the bowel, he found sodium chloride and carbonate too irritating in the high concentrations required for this purpose. However, sucrose enemas, from 20 to 40 per cent, given twice daily for eight consecutive days, cured a large proportion of cases. Soap solution (1 per cent), it is asserted, kills the pregnant females of *Oxyuris*. Vinegar (from 30 to 100 per thousand) enemas are also recommended in oxyuriasis.

Simple Oil Enemas.—These are essentially evacuant enemas; but, as they are to be retained for many hours, usually over night, they are given with the technic of the retention enema. The indications for simple oil enemas are: 1. To soften feces, in constipation characterized by the formation of hard scybala and in that due to partial obstruction of the colon. 2. For evacuant action, in so-called spastic constipation, in pelvirectal constipation, and in any other form of constipation in which oral administration of cathartics is contraindicated by gastric disturbance. 3. For soothing action, in excessive colonic and rectal irritability, in colitis, and in proctitis. 4. It has been suggested that oil enemas might inhibit absorption of toxic products. That the oil has the power of removing substances soluble in it is shown by the fact that it is passed dark yellow or olive green and of offensive odor. We have no definite knowledge, however, of the degree to which this property might be of clinical value.

The chief contraindication to oil enemas is diarrhea, and mainly because, in this condition, the oil would not be retained for a sufficient length of time to be of use; although another objection against the introduction of saponifiable oils would be the fact that excessive peristalsis may carry intestinal juices far down the colon, and the results of the oil digestion might still further increase the irritation.

To be well borne, the oil must be pure and free from rancidity, of an acidity not exceeding from 40 to 55 (Fleiner). This is more important than that it come from a certain source. Thus, poppy seed oil, oil of sesame, or cottonseed oil, when pure, are just as good for this purpose as olive oil. It would seem that petrolatum would be preferable to all of these, as it can never become irritant.

The following technic is recommended: For self administration of the oil, the patient should have everything prepared before going to bed, so that he does not have to get up after having taken the injection. The bottle of oil is placed in a basin of hot water until it has acquired blood heat (100 F.). An ordinary fountain syringe might be used, provided the nozzle has a sufficiently large bore to permit the oil to pass. Though it is intended that the oil be introduced slowly, the bag usually has to be hung 2 or 3 feet high, owing to the viscosity of the oil, which makes it run rather slowly. The clip should be placed within easy reach of the patient. Having poured the oil into the bag, the patient lies on the left side with a folded towel underneath the buttocks. The nozzle is inserted into the anus, and the oil permitted to flow. Should the patient experience distress or desire to move the bowel, the flow of the oil is checked and the patient remains quiet until the desire has passed away. It might then be possible to introduce an additional quantity of oil. It is usually best, however, to be satisfied with the introduction of an amount that can easily be retained. A piece of absorbent cotton or a woman's sanitary towel or both may be applied to prevent accidental soiling of the bed, for the passage of flatus may be accompanied by a spurt of oil. If the injection produces discomfort and interferes with sleep, it may be taken early in the morning, and the patient may lie in bed for three or four hours afterward. The patient should understand that, unless the oil remains in the intestine for several hours at least, satisfactory results cannot be expected. The total quantity to be injected depends, therefore, on the patient's ability to retain it. This is so variable that no definite quantity can be stated. The principle to be followed is to have the patient gradually increase the amount injected on successive nights, until a satisfactory amount can be introduced and retained. The patient may not be able to retain more than 70 cc. at first, but is likely to retain in course of time as much as 250 and even 500 cc. For children, from 50 to 150 cc.; for infants, 15 cc. suffice. When scybala disappear, and soft mushy stools are passed, the quantity introduced as well as the frequency of injections is gradually diminished. Just as soon as satisfactory daily evacuations have been secured and the patient's distress has been relieved, the injections may be given on alternate nights, unless resumption of daily injections is necessitated by the patient's condition. Later on the injections are given every third night and finally only on the evening of the day on which the bowels were not opened. A single injection may cause daily evacuation for several successive days.

---

[65] Fletcher, William: Bull. Inst. M. Research, Federated Malay States, 1924.

[66] Van der Togt: Geneesk. Tijdschr. v. Nederl.-Indie **61**: 395, 1921.

When the injection acts well, it will be followed by a very soft bowel movement in the morning. If the morning evacuation is not obtained, an enema of physiologic sodium chloride solution should be taken in the morning after breakfast.

Evacuant Enemas.—Whenever an abnormal accumulation of feces occurs in the descending or pelvic colon or in the rectum, the bowel should be thoroughly washed out before other treatment is instituted. It is really not rational to upset motor and secretory functions all the way down the bowel by giving a physic in order to clear out the lower end of the tube when this can be done so much more directly by washing out from below. Preeminently is the enema the only evacuant to be considered when intestinal obstruction is present or suspected, in which cathartics merely stimulate the already overstimulated bowel above the site of the obstruction, increasing pain and vomiting and aggravating shock and the injury existing at the point of obstruction. Hence the patient's chances for recovery decrease as the use of cathartics is pushed. Here all efforts to make the bowel move should be from below; and evacuant enemas, in increasing order of potency, should be repeated every three or four hours, care being taken not to overdistend the colon, until success is secured or the uselessness of the procedure becomes evident, when operation should be instituted without delay, within twelve hours, if possible.

Whether high or low, large or small, hot or cold, simple or medicated, enemas should be employed to secure evacuation in any one case depends on the conditions present. If the rectum merely is to be emptied of feces, 0.5 liter injected rapidly with the patient in the sitting posture suffices. If the most thorough possible cleansing of the bowel is aimed at (colonic flushing), the largest possible quantity of warm water—from 1 to 2 liters—is slowly introduced with the patient recumbent or, better still, in the knee-chest position. In either case, soap (about 1 to 2 per cent) is the most generally useful addition. Large colonic flushings, however, must not be employed for many weeks in succession, as they are liable to increase the atony of the bowel and of the abdominal musculature. On the other hand, a small (0.25 liter), cool enema rather quickly injected into the bowel, to stimulate it to evacuation, may be considered one of the least objectionable procedures, even when employed quite habitually. In such cases, a progressive lowering of quantity and of temperature should be aimed at, the patient always first attempting to have a bowel movement without its aid.

When the soapsuds enemas fail to secure the desired results, a purgative enema may be resorted to. A small evacuant enema of magnesium sulphate, 60 Gm.; glycerin, 30 cc., and water, 120 cc., is popular in some hospitals. A larger purgative enema is composed of hot soapsuds, 0.5 liter, with magnesium sulphate, 60 Gm.; glycerin, 60 cc., and oil of turpentine, 15 cc., emulsified by yolk of egg. Another useful combination is 0.5 liter each of milk and molasses (or honey). One or the other of these rarely fails to secure the evacuation, if it is physically possible.

In the treatment of tympanites, volatile irritants seem more efficient than the nonvolatile cathartics: evidently the former appeal more especially to the gas-evacuating mechanism than the latter. Volatile agents, such as asafetida or oil of turpentine, are best administered in the form of an emulsion, and it is under this heading that their prescribing has been discussed.

Colonic Irrigation.—Permitting fluid to run into and out of the bowel by means of a two way irrigator, until the washings return clean, secures the most thorough possible cleansing and medication of the colon. Thus, in colitis, especially the ulcerative form, irrigating the colon with huge quantities (from 16 to 20 liters) of water as hot as can be borne (120 F.), preferably with the patient in the knee-chest posture, gives good results. Such irrigations—the so-called return flow enema—are also frequently the sovereign remedy against postoperative gas pains. Hot colonic irrigation is of value to raise low body temperature in collapse. More questionable is the use of cool irrigation as an antipyretic measure. Hot and cold colonic irrigations are also employed to induce vascular and possibly other changes in adjoining organs, such as the prostate or the internal generative organs of the female.

(To be continued)

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

DIGITALIS DISPERT.—An extract of digitalis, obtained by extraction of digitalis leaves with cold water and evaporation of the extraction by a special process. It is standardized by the minimum lethal dose frog method of Straub (*Arch f. exper. Path u Pharmakol.* 80:52, 1916-1917) so that 1 Gm. represents 1,900 lethal frog doses.

Actions and Uses—Those of digitalis. It is the aim of the manufacturer to offer in digitalis dispert the entire water soluble activity of digitalis glucosides closely resembling their state and proportion in the leaf.

Dosage.—0.08 Gm. (1⅕ grains) from three to six times daily. Digitalis dispert is supplied in the form of tablets only.

Manufactured by Krause Medico Gesellschaft m b H, Munich, Germany (Schering & Glatz, Inc, New York, distributor) No U. S. patent. U S trademark 194,834

Digitalis Dispert Tablets 0.08 Gm.: Each tablet represents 150 lethal frog doses

Digitalis dispert is prepared by extracting specially harvested, air-dried, digitalis leaves with cold water by a special maceration process The solution thus obtained is brought to dryness by a special spray process of evaporation

Digitalis dispert is a light brown powder of somewhat aromatic odor and bitter taste

PERTUSSIS BACILLUS VACCINE (See New and Nonofficial Remedies, 1925, p. 354).

Parke, Davis & Company, Detroit.

Pertussis Immunogen—A bacterial antigen (ectoantigen) obtained by agitating live pertussis bacilli with physiological solution of sodium chloride and separating the liquid from the organisms; the extract is free or nearly free from bacterial cells and toxin and is preserved with phenol There is some evidence that this material will yield approximately the same results as the ordinary pertussis bacillus vaccine Pertussis immunogen is marketed in packages of one 10 cc. vial *(Bio 315)*, each cubic centimeter containing the antigens from 2,000 million of bacteria.

PNEUMOCOCCUS VACCINE (See New and Nonofficial Remedies, 1925, p. 355).

Parke, Davis & Company, Detroit.

Pneumococcus Immunogen—A bacterial antigen (ectoantigen) obtained by agitating live pneumococci Types I, II and III with physiological solution of sodium chloride and separating the liquid from the organisms; the extract is free or nearly free from bacterial cells and toxin and is preserved with phenol. There is some evidence that this material will yield approximately the same results as the ordinary pneumococcus vaccine. Pneumococcus immunogen is marketed in packages of one 10 cc. vial (*Bio 305*), each cubic centimeter containing the antigens from 2,000 million of bacteria.

WATER: ENOUGH, MORE, OR LESS

Three fourths of the protoplasm of the body cells consists of water; the body fluids and secretions are even richer in this substance. After a little consideration, every one appreciates that water plays an important part as a "universal solvent"; at any rate, substances dissolved in it seem to react with greater ease and speed than when dissolved in other mediums. Consequently the physiology and biochemistry of living organisms include prominently the rôle of water. They deal not only with ingested water but also with that formed through the oxidative processes of the body. Thus, there are endogenous as well as exogenous sources of water. Its functions are not merely to act as a medium in which the chemical changes of metabolism occur; water also assists in the removal of waste products and the dissipation of heat. Rowntree[1] has remarked that, in relation to the duration of life, water occupies a position intermediate between food and oxygen; it is more vital than the former, and less vital than the latter.

Medicine is not unfamiliar with the circumstance that some substances which in certain quantities or concentrations may represent a blessing to the body are also liable to produce detriment when they are used in undue abundance. Hydrochloric acid shows its physiologic uses in the gastric functions; but even moderately larger concentrations act as irritants with marked severity. Some of the familiar poisons become wholesome drugs when their intake is reduced to a sufficiently low level.

Even water has its "pathology." Rowntree has described phenomena of what he terms "water intoxication" following introduction of very large amounts of the fluid under certain experimental conditions. In diabetes insipidus, the water balance is set at a level higher than normal. The level can be lowered immediately by the subcutaneous administration of the extract of the posterior lobe of the hypophysis. Subsequent to the use of the extract, the ingestion of water in the large amounts to which the patient has become accustomed results in marked toxicity. Larson, Weir and Rowntree observed patients who developed headaches, nausea, asthenia, incoordination, marked sweating and, in one instance, mild subcutaneous edema under these conditions. These findings are in accord with those of Miller and Williams. Patients with chronic nephritis and hypertension who took water in quantities up to 10 liters a day developed headache, dizziness, restlessness, chills, fulness of the abdomen, vomiting, dyspnea and cramps in the legs, marked increase in weight, and increase in blood pressure. Edema and the collections of fluid in undue quantities in some of the body cavities and tissue spaces represent better known instances of water out of place. Treatment of such conditions, often of a distressing nature, calls for the mobilization and transport of water. Nearly a quarter of a century ago, Widal[2] indicated the importance of a diet low in chlorides for certain cases of nephritic edema. Such a regimen may be followed by diuresis and reduction of the edema. Sometimes more than this is necessary to effect a relief. At the Mayo Clinic, Keith, Smith and Whelan[3] have secured beneficial results in selected patients with edema and ascites by carefully controlled diets low in water content. Many of the common foods of superior nutritive advantage contain considerable water. Deprivation of water in the intake thus may call for skill in dietary selection, particularly when the allowance is to be reduced to a total of 1,500 cc. daily. The possibilities of low fluid diets are likely to receive further detailed consideration in the near future.

LIMITATIONS OF COD LIVER OIL IN RICKETS

The discovery that nutritional disorder is the etiologic feature in the development of rickets, and the demonstration of some of the dietary and environmental factors, in contrast to endogenous agencies, concerned in the genesis of rachitic conditions are among the most notable contributions of recent experimental medicine. First of all, the diagnosis of the disorder at all stages has been made more precise through the aid that the newer knowledge of blood chemistry and roentgenologic technic of examination have contributed to the more familiar routine of clinical observation. Secondly, the contributory etiologic rôle of inappropriate or inadequate mineral nutrients in the diet, the effects of deficiencies of vitamin D—the specific antirachitic food essential—and the need of sunlight with its potent radiations in the ultraviolet region of the spectrum have become recognized. Furthermore, animal experimentation has been successfully called on to contribute to the elucidation of all aspects of the rickets problem.

[3] Keith, N. M.; Smith, Florence H., and Whelan, Mary: The Therapeutic Use of Diets Low in Water and in Mineral Content, Arch. Int. Med **37**: 550 (April) 1926.

Incident to this study it has happened that cod liver oil, long recognized as having antirachitic potencies, has been heralded as a veritable specific alike for the prevention and the cure of rickets. The widespread prevalence of this disease and the extremely untoward consequences of its unchecked progress for the person involved have served to give unusual prominence to rickets in the mind of the layman as well as of the physician. Under the unfeigned encouragement of the medical profession, child welfare agencies everywhere have preached the doctrine of the liberal administration of cod liver oil in infancy. The undoubted success in the large reduction of infantile scurvy as the result of educational propaganda has served to spur on the efforts of the promoters of public health. The public has been informed through numerous channels, including even the legitimate lay advertising in the sales promotion of manufacturers. The antirachitic cod liver oil has taken its place with orange juice and other antiscorbutics among the desiderata of children's dietaries.

Of this there can be little criticism. The time has arrived to take account of the hygienic accomplishments of the new procedures in the light of their claims. The importance of such control investigation of newly inaugurated health habits is well illustrated in connection with the efforts at goiter prophylaxis. The relation of the malady to a deficiency of iodine has been clearly established. The preventive and curative effects of small doses have likewise been demonstrated beyond question. But the consequences of undue enthusiasms created by such knowledge and expressed in the universalization of administration of iodine by mass methods are beginning to raise protests on many sides.[1] Hence it may be asked to what extent the promotion of the use of cod liver oil in infancy is on a basis that is defensible from every standpoint. Is it effective? Does it involve possibilities of unsuspected harm? Is it worth while? Should it be modified in any way?

Evidence is already available to suggest that the highest expectations are not consistently realized. The commonest reaction to such reports is to question the dosage or potency of the cod liver oil given. Since it has become possible to standardize the product through laboratory tests, there is less excuse for centering all criticism on the quality of the therapeutic agent employed. Thus, Wilson's[2] study of New York infants, aged from 1 to 3 months, born in the spring and summer of 1924, receiving graduated doses of from one-half to 1½ teaspoonfuls of a biologically tested cod liver oil, revealed the development of clinical rickets in 91 per cent of the subjects. A more intensive study of forty-seven infants, aged from 2 weeks, born in the winter of 1925, receiving daily doses of 1, 2 and 3 teaspoonfuls of biologically tested cod liver oil, showed the development of clinical rickets in 68 per cent of the cases, as compared with 76 per cent of the control series of thirty cases. Ninety-seven per cent of infants born in the summer, and 91 per cent of infants born in the winter who received cod liver oil showed roentgenographic evidence of rickets, as did 97 per cent of the infants born in the summer, and 98 per cent of infants born in the winter who did not receive cod liver oil. There did not seem to be any relation between the degree of rickets observed and the amount of cod liver oil received. Furthermore, a comparison of the degree and incidence of rickets observed in infants receiving and not receiving cod liver oil did not reveal any striking difference. Another significant feature of these New York patients is that the concentration of calcium and inorganic phosphorus in the serum of infants under 5 months of age with early clinical and roentgenographic evidence of rickets was within the normal range. This suggests that perhaps the rickets must be marked and of some duration to show regularly a reduction of the inorganic phosphorus in the serum.

This report, by no means isolated in its findings, must not be received in gloom or allowed to spread discouragement. It was true, even in the New York infants, that those receiving cod liver oil showed rickets that healed earlier than that of the control series. Wilson asserts that the development of rickets in the babies born in winter, in whom preventive cod liver oil therapy was instituted in the first month of life under special supervision, is not easily explained, particularly in comparing the findings with those in the control group. A consideration of the age period when the greatest incidence of rickets was observed, namely, in the fourth and fifth months, suggests that the findings described may be related to the rate of growth, since the rate of growth at this age period is the most rapid in infancy. The rapid growth of the majority of the infants and their general excellent condition may therefore bear some relation to the findings here observed. If the disease described is rickets, Wilson adds, it would seem to be universal in young infants. Her observations were conducted under the limitations imposed by an outpatient clinic; however, one can scarcely expect that this should not be representative of average home conditions among the less well-to-do. It behooves us to consider more seriously than is currently being done whether the inorganic or other food factors aside from vitamin D are not also involved in the rachitic tendencies so widely observed. In the animal laboratory, an adequate intake of well selected mineral nutrients is a potent help in averting rickets. More attention must perhaps be paid not only to dosage but also to the assimilation of cod liver oil. Bloch of Copenhagen has already sounded a warning in this respect. The lesson of recurrent rickets recently taught by Hess[3] indicates the need of unremitting vigilance and persistence in treatment. The unqualified success attained with cod liver oil under carefully controlled conditions of many clinicians should give assurance of the wisdom of its inclusion in prophylaxis. What is needed above all at present, however, is a better understanding of how rickets may be averted in the home as well as in the well ordered clinic.

HUMAN CARRIERS OF TETANUS SPORES

The incidence of tetanus has always been greater in times of war than at other periods.[4] This menace was well realized during the World War, so that prophylactic measures against the disease were widely used. How successful they were is indicated by the statement, for example, that there were 1,450 cases of tetanus among the wounded sent to England during the war, and but for the use of antitetanic serum there would presumably have been 14,000 cases. Practically all mammals are susceptible to tetanus. The etiologic agent, the tetanus bacillus, is found quite frequently in the intestinal contents of herbivorous animals, notably the horse. These animals become responsible for the distribution of the micro-organism through their excreta. Highly manured areas are particularly liable to promote the occurrence of tetanus in soil-contaminated injuries such as war wounds usually represent. The disease may also be transmitted to new-born infants in places where the custom of dressing the severed umbilical cord with earth is followed, or where the dressings that are applied may be contaminated by soil. Tetanus neonatorum remains more common than might be supposed; according to Vaughan there are ten, possibly a hundred, deaths from it for every death from tetanus in soldiers.

The records of a single large state for a period of the last four years show 245 cases of tetanus with a mortality of 67 per cent. The histories in many instances suggest that the infection may have been of fecal origin. The fact that man can act like animals as a carrier of tetanus has long been known. The extent of this possibility has not been fully realized, the general opinion being that only those persons who are in intimate contact with horses are likely to be human carriers of the bacillus. Yet there are records published from many countries, including England and Germany as well as China, that attest the presence of the spore-bearing anaerobe, the tetanus bacillus, in the feces of persons. Thus, in China the surveys by Ten Broeck and Bauer showed that from one fourth to one third of the human fecal specimens examined harbored the micro-organisms.

The first definite results available from larger numbers of persons in the United States have just been recorded by Bauer and Meyer.[5] Out of nearly five hundred specimens from California, one fourth were found positive for tetanus spores. Confirmatory evidences have been secured from various states in sufficient numbers to indicate that other parts of the country are not devoid of human carriers of tetanus. Sex, age and occupation apparently do not play a part in their distribution, nor have atoxic strains of the bacilli been found. The extension of these studies is eminently to be desired; for the evidence that approximately 1 Gm., or 15 grains, of feces from every fourth person in the single state studied contains tetanus spores leads to the conclusion, as Bauer and Meyer believe, that an enormous amount of infectious material capable of producing fatal disease under favorable circumstances is being discharged daily by tetanus carriers. One cannot avoid the suspicion that the human carrier is more or less immune to the type of bacilli that he carries; he is, nevertheless, dangerous to those who are not carriers or who carry other types. Fortunately, the improved methods of sewage disposal tend to remove human dejecta from the possibility of contact with man and from the domain of soil contamination. The ubiquity of fecal bacteria compels us, however, to keep constantly in mind any possibilities of even indirect menace that they may represent—particularly when the Fourth of July threatens.

Current Comment

REVOCATION OF MEDICAL LICENSES ON TESTIMONY BY DEPOSITION

An obstacle in the way of proceedings to revoke licenses to practice medicine is sometimes the inaccessibility of essential witnesses. Missouri undertook to overcome this obstacle by authorizing the taking of testimony by deposition in the same manner and under the same rules and practice as govern the taking of depositions in civil cases. Such depositions are taken by duly authorized officers, empowered to compel witnesses to appear and testify. The State Board of Health, the licensing body in Missouri, is itself without power to compel the attendance of witnesses and the production of papers by subpena in any case. The constitutionality of such procedure was attacked on the ground that it denies the person whose license is at stake the "due process of law" to which he is entitled under the federal constitution. In a recent case,[6] however, the United States Supreme Court sustained the Missouri statute. The license of the plaintiff in error, Leon Hurwitz, was revoked by the state board of health because he had unlawfully produced an abortion. The proceedings were reviewed by the state circuit court and the supreme court of Missouri,[7] but both courts sustained the action of the board. Hurwitz thereupon carried the case to the United States Supreme Court. In affirming the decisions of the courts below and denying Hurwitz the relief he sought, the supreme court pointed out that the accused is afforded due process of law if he is given reasonable notice and reasonable opportunity to be heard, due regard being had to the nature of the proceedings and the character of the rights affected by it. These requirements, said the court, are satisfied by the procedure authorized by the Missouri medical practice act, as that procedure was applied by the state board of health, since—

[5] Bauer, J. H., and Meyer, K. F.: Human Intestinal Carriers of Tetanus Spores in California, J. Infect. Dis. **38**: 295 (April) 1926.

[6] State of Missouri ex rel. Hurwitz v. North, — U. S. —; 46 S. Ct. 384; 70 L. ed. 406, decided April 12, 1926.

> The notice prescribed was reasonable. The testimony of all witnesses who appeared before the board was taken and recorded, including that of the plaintiff in error. Although the statute did not authorize the board to issue subpenas, the plaintiff in error was authorized, as the state court held, to take the depositions of witnesses who did not voluntarily appear. Officers who take depositions are authorized to compel witnesses to attend and give testimony. The depositions, when taken, may be read at the hearing before the board. The procedure prescribed and followed here gave ample opportunity to plaintiff to make a defense to the charges preferred and there was no denial of due process.

The decision is important in that it points a way to simplify proceedings looking toward the revocation of licenses. If the law of a state already authorizes the taking of testimony by depositions, the licensing board can now proceed more confidently than before. If, however, the state law does not authorize the taking of testimony in this way, it may well be amended to accomplish that end. Otherwise, the difficulty and expense of procuring the attendance of witnesses will continue, as at present, a serious obstacle to the revocation of licenses that ought to be revoked.

THE HEALTH NEEDS OF NEW YORK

New York is one of the greatest municipalities in the world. It is significant, therefore, to learn how a committee of physicians, giving special study to its conditions, visualizes the health problems of such a community. The Public Health Committee of the New York Academy of Medicine has recently summarized the problems facing the city with regard to its health needs as follows: decentralization of population and better housing conditions; strengthening of the sanitary safeguards in food and milk production and distribution; adequate sewage and garbage disposal; systematic development of health education based on sound principles; supervision and control of occupational hazards; extension of outdoor recreational facilities, and suppression of obnoxious and deleterious odors, dust and the smoke nuisance.[8] The absence of direct reference to active disease, epidemics and other bacterial menaces should not be interpreted as indifference to such factors. Disease control is a well recognized aspect of public health control. Indeed, the New York committee has given prominence to the baffling nature of some of the communicable diseases of the central nervous system and has suggested the organization of a commission for the study of the etiology, pathology and epidemiology of these. It has also called attention specifically to the inadequate control of whooping cough, which stands as the third highest cause of death among the acute infectious diseases. But the attempted education of a municipality to make budgetary appropriations in the direction of personal prophylaxis and preventive hygiene shows how far the medical profession has traveled toward disease prevention. In many respects the physician is necessarily an individualist. Stryker[9] has insisted that no friend of the medical profession could bemoan this or wish to change it. And yet, he adds, there are times when the individual physician, oppressed by the manifold duties and responsibilities which flow from the high calling which he follows, is prone to forget that the attainment of the great ends to which he has dedicated his life—the safeguarding and protection of the public health—can best be served by combined action rather than by working alone. The altruistic efforts of the Public Health Committee of the New York Academy of Medicine indicate how well our profession can serve in this respect.

PROTECTING THE PUBLIC IN MISSOURI

Apparently, the public and the medical profession of Missouri are finding the cleaning of their Augean stables of medical licensure a difficult task. The situation reveals again the unholiness of any alliance between public health and politics, and even more, the difficulty of divorcement when such an alliance is once perpetrated. In his presidential address before the Missouri State Medical Association recently, Dr. Emmett P. North made an impassioned plea for a final fumigation so that Missouri may make a clean start. He called attention to the weakness of the medical practice act, and to the facts that Missouri has three out of six of the nonreputable schools in the United States, that there is an apparent reticence on the part of the newly established state board of health to take any drastic action against recognized offenders, and that the time is ripe for all persons interested in honest medical practice to unite on a medical practice act which will serve to protect the public. In the *Missouri State Medical Journal* for June, the editor, Dr. E. J. Goodwin, enforces the statement of Dr. North, and in the name of the organized medical profession calls on the newly established state board of health to organize officially, to revoke licenses obtained through fraud, and specifically to prosecute vigorously the revocation of license of Dr. R. B. Horton, whose record in relation to the licensure scandals in Missouri has appeared both in medical periodicals and in the public press. The insinuation has been made repeatedly that medical licensure in Missouri has been, and is, closely linked with the general conduct of state affairs, and that the governor of the state has not been above mingling in these matters to the interest of those who have sought and to whom he has owed political preference. The recognition and rewarding of those who aid our office-holders to high positions is not an unusual feature of county, state, or even national American politics. However, most of the great statesmen of all time have recognized that the care of the public health is the first interest of the state. The unqualified, incompetent, dishonest practitioner, licensed to practice by the state and practicing his type of medicine while skulking in the shadows of legal recognition, is a greater menace to public health than the nostrum vender or the forthright charlatan. If the members of the state board of health of Missouri are sincere in their wish to fulfil honorably the positions to which they have been appointed and to protect the public against unqualified practitioners, they will not hesitate to take up the challenge issued by the officers of the state medical association, and to prosecute to the utmost such obvious offenders as have been called to their attention.

WHAT ABOUT YOU?

This month, an information card is being sent from the headquarters office of the American Medical Association to every physician in the United States and Canada. On it, the recipient is asked to place certain information to be used in compiling the tenth edition of the American Medical Directory, which is now being prepared in the biographic department of the Association. The directory has assumed a place of importance in American medical life and has established itself as one of the most significant of the altruistic efforts of the Association in the interest of the medical profession and for the protection of the public. In it, as in no other published directory, may be found dependable data concerning physicians, hospitals, organizations and medical activities. Physicians who receive the card are asked to fill it out and return it promptly to this office, whether or not any change has occurred in the information specified. Should the reader fail to receive the card before the first of August, he will aid by writing to the headquarters office, stating that fact and indicating whether or not any change is to be made in the information published in the current issue of the directory.

Cost of Public Health Nursing.—In the large cities surveyed in 1924 by the U. S. Public Health Service, the municipal expenditures for public health nursing varied from 1.5 cents to 36.6 per capita, with an average of 15.4 cents, as compared to 9.5 cents for the same group in 1920. It is evident that such an expenditure falls far short of the average cost per capita of 83 cents proposed in the "ideal" plan. It should be remembered, however, that this plan included the cost of private as well as official nursing, and that the figures for the 1924 surveys include only the municipal service. It should be noted that the estimate of 83 cents per capita is equal to or greater than the sum which is now being expended for all strictly health work by many cities, including nursing services. This does not mean that the estimate for nursing is high, but that the expenditure for health work is low.—Cumming, Hugh: *Pub. Health Rep.* **41**:380 (Feb. 26) 1926.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CONNECTICUT

Memorial to Beaumont.—A memorial will be unveiled at Lebanon, Conn., June 29, to Dr. William Beaumont, the pioneer American physiologist and distinguished member of the U. S. Army Medical Corps. Dr. Beaumont was born in Lebanon, Nov. 21, 1785, and made most of his observations on Alexis St. Martin, a Canadian, who suffered a permanent gastric fistula, following an accidental gun-shot wound. The Michigan Medical Society, to which Beaumont reported his studies in 1827, erected a monument on Mackinac Island near the spot where these immortal studies were begun. Lafayette B. Mendel, Ph.D., Sterling professor of physiologic chemistry, Yale University Medical School, is president of the Beaumont Medical Club.

Clinical Congress of State Society.—The second clinical congress of the Connecticut State Medical Society will be held in Sprague Memorial Hall, Yale University, New Haven, September 21-23. There will be nineteen papers presented, a round table discussion on periodic health examinations the first evening, and a smoker at the New Haven Lawn Club the second evening. The university has assigned a dormitory for the use of the congress, where rooms at $1.50 per night may be secured; if hotel accommodations are preferred, reservations should be made directly with the hotel. The university dining hall will be in operation, and luncheon will be provided for members without extra charge. Twenty-four hour telephone service will be maintained so physicians may be kept in touch with their offices. Among those who have accepted invitations to speak are Dr. John Shelton Horsley, Richmond, Va.; Dr. Hugh Cabot, Ann Arbor, Mich.; Drs. *Henry A. Christian and Charles F. Painter, both of Boston*; Drs. Edward L. Hunt, New York; Arthur C. Christie, Washington, D. C.; Robert B. Osgood, Boston; John O. Polak, Brooklyn, and Roger H. Dennett, New York. There will be a fee of $10, which includes admission to all sessions, the luncheons, smoker, parking space and garage, and a copy of the abstracts of papers presented. Inquiries should be addressed to Dr. Creighton Barker, 129 Whitney Avenue, New Haven.

FLORIDA

State Medical Election.—Dr. Henry Mason Smith, Tampa, was elected president of the Florida Medical Association at the recent annual meeting in Gainesville; Drs. Frederick J. Waas, Jacksonville, James Maxey Dell, Gainesville, Arthur G. Fort, Miami, vice presidents, and Dr. Shaler A. Richardson, Jacksonville, secretary-treasurer (reelected). The next meeting will be at West Palm Beach.

Midwives Fined.—The state board of health notes that Nettie Troublefield, Miami, was fined $54.84, April 8, for practicing midwifery without a certificate from the city department of health, and that Druscilla Edden was fined $29.85 at Miami, March 23, "for attempting to practice a certain branch of medicine on a patient after having been refused a certificate to practice midwifery."

GEORGIA

University News.—The University of Georgia conferred the degree of doctor of medicine on twenty-three graduates of the medical school, May 31, among whom was Loree Florence, who, according to the Augusta *Chronicle*, is the first woman to receive the degree of doctor of medicine from the University of Georgia. Following a meeting of the board of directors of the medical college, the resignation of Dr. Eliot R. Clark, professor of anatomy, was announced; Dr. Clark goes to the anatomy department of the University of Pennsylvania School of Medicine, Philadelphia.

Alumni Week Clinics.—The state board of health, cooperating with the School of Medicine of Emory University and the U. S. Public Health Service, conducted clinics and lectures, June 7-11, devoting the afternoons especially to venereal disease, when graduate physicians were given an opportunity to assist in the treatment of patients. Atlanta hospitals kept "open house," and physicians over a large territory were invited to be present. A complimentary dinner was given by the Atlanta Alumni of Emory University. There were also surgical and medical clinics, clinicopathologic conferences, and symposiums. This postgraduate study was the seventh annual institute-clinic on venereal diseases of the state board of health in cooperation with the Public Health Service.

ILLINOIS

Society News.—Dr. Herman L. Kretschmer, Chicago, addressed the Sangamon County Medical Society, Springfield, June 3, on "Urology and Its Relation to General Medicine and Surgery," illustrated by lantern slides.——The Illinois State Medical Society, at its recent annual meeting, established a section of radiology. There are now said to be five state societies which have sections of radiology—Wisconsin, Texas, Massachusetts, Louisiana and Illinois.——Dr. Gustaff H. Mundt, Chicago, president-elect of the Illinois State Medical Society, addressed the Vermilion County Medical Society, June 1, on "The Value of a Medical Society to the Physician."

Chicago

University News.—Graduates of Rush Medical College had contributed $230,000 up to June 5 toward the alumni quota of $2,000,000 in the University of Chicago's endowment drive; their self-made goal is $250,000. Graduates of Rush in forty-one states, three territories and five foreign countries have subscribed; 500 Rush Alumni in Chicago gave $124,475.

Society News.—The last meeting of the year of the Chicago Council of Medical Women will be June 22, at the Men's City Club, 315 Plymouth Court. Dinner at 6:30 p. m. at $1.50 per plate will precede the meeting; the chief speaker will be Dr. Georgine M. Luden, an associate in the research department of the Mayo Clinic, Rochester, Minn.; the other guest of honor and speaker will be Dr. Bertha Van Hoosen.——Dr. Isaac A. Abt was elected president-elect of the Chicago Medical Society, June 15, and Dr. Frank R. Morton, secretary.

Summer Clinics at Cook County Hospital.—Under the auspices of the Chicago Medical Society, the staff of Cook County Hospital will give two courses of two weeks of clinics, July 19-31 and August 1-14. There will be no fee and no diplomas given, and admission will be by card only, which will be sent to those who register early in reply to more than 10,000 letters mailed by the Chicago Medical Society to physicians in the state. The number which can be accommodated is limited. The clinics will cover general medicine and surgery and many of the specialties.

Personal.—Dr. Frank Billings received the honorary degree of doctor of science at the commencement exercises of Northwestern University, June 14.—A dinner dance, under the auspices of the North Side Branch of the Chicago Medical Society, was given at the Edgewater Beach Hotel, June 12, in honor of Dr. Charles J. Whalen, a former president of the Chicago Medical and the Illinois State Medical societies.——Dr. William Allen Pusey, formerly President of the American Medical Association, gave the commencement address at the University of Illinois School of Medicine, June 12.——Dr. John Ridlon received the honorary degree of doctor of science at the commencement of Tufts College, Boston, June 14.——The honorary degree of doctor of science was conferred on Dr. Frank Smithies by Washburn College, Topeka, Kan., June 2.——Dr. Bertha Van Hoosen recently received the honorary degree of LL.D. from Loyola University.

LOUISIANA

University News.—The senior class of Tulane University of Louisiana School of Medicine, New Orleans, June 8, presented to the school a portrait of Dr. Rudolph Matas, professor of surgery, which was painted by Harry Armstrong Nolan.

Supreme Court Refuses Chiropractors' Writ.—Having been sentenced by Judge Byrnes, New Orleans, to ten days in jail and a fine of $50 for practicing chiropractic in violation of an injunction issued by the court two years ago, Walter W. and Joseph B. Fife appealed to the state supreme court for a writ to restrain the judge from enforcing the sentence. The supreme court refused, May 12, to issue the writ. This is said to be the second time the Fife brothers have been punished for contempt of court (THE JOURNAL, July 7, 1923).

House Passes "Hospital Abuse Bill."—The lower house of the state legislature passed a bill, June 3, which would require each applicant for admission to the charity hospitals in New Orleans and Shreveport, except in cases of immediate emergency, to fill out blanks to show whether the applicant is able to pay. The bill provides that an applicant who is able to pay for his care and treatment shall be rejected, and that if after such patient has been admitted it is found that he misrepresented his financial condition, he will be subject to prosecution.

MARYLAND

Personal.—Dr. Susanne R. Parsons of the Baltimore City Health Department has resigned, effective, June 15.——H. A. B. Dunning, Baltimore, has been awarded the Remington Honor Medal of the New York Branch of the American Pharmaceutical Association for successfully directing the campaign to raise $1,000,000 for a headquarters building for the national pharmacy association.——Dr. Charles W. Maxson, Baltimore, was elected president of the Alumni Association of the Medical Department, University of Maryland, at the recent annual meeting in Baltimore.

Hospital News.—Largely with funds left by Mrs. Helen Turner, a building will be erected for the James Lawrence Kernan Hospital and Industrial School for Crippled Children, and six beds at the Eudowood Sanatorium will be provided. The new building at Kernan's Hospital will be especially equipped to treat diseases of the spine and bones; construction will start this summer. Mrs. Turner bequeathed about $80,000 to each institution, which will be increased to about $100,000 on the death of certain life tenants. About $45,000 has been raised from other sources to help pay for the new building.

MICHIGAN

Postgraduate Conference.—A postgraduate conference was held in Michigan at Alpena, May 6, to which some physicians traveled as far as 250 miles; every resident physician of Alpena was present, and the parent teacher association and the Rotary Club participated in the program of the conference. Three hundred other citizens attended the meeting. Dr. William H. Marshall, Flint, spoke on "Physical Examination with Demonstration," and Dr. Walter H. MacCraken, dean and professor of pharmacology and therapeutics, Detroit College of Medicine and Sugery on "Advances in Therapeutics." Following the program, there were dancing and light refreshments.

Personal.—Dr. Albert C. Kerlikowske has been appointed chief resident physician at the University Hospital, Ann Arbor.——Dr. Silas B. Frankhauser has been elected mayor of Hillsdale.——Dr. Roy C. Perkins has been elected chief of staff of Mercy Hospital, Bay City.——Dr. James H. Dempster, Detroit, has been elected president of the Wayne County Medical Society for the ensuing year.——Dr. S. Rudolph Light has been elected president of the Kalamazoo County Tuberculosis Association.——Dr. Gertrude O'Sullivan has resigned as city health officer for Port Huron.——Dr. Hugh Cabot, dean and professor of surgery, University of Michigan School of Medicine, Ann Arbor, took charge of Sir Holburt Waring's surgical clinic at St. Bartholomew's Hospital, London, England, from May 31 until June 12, and during that time, according to the *Lancet*, delivered two lectures at the medical school on "Nontuberculous Infections of the Kidneys," another on "The Present Position of Prostatic Surgery," and another on "Tuberculous Disease of the Kidney."

MINNESOTA

Personal.—Dr. Alfred E. Comstock, St. Paul, has been elected secretary of the state board of medical examiners to fill the vacancy caused by the death of Dr. Thomas McDavitt; the office of the secretary has been moved to 636 Lowry Building, St. Paul.——According to the *Journal-Lancet*, Dr. Walter L. Taft will be a candidate for the office of city coroner of Minneapolis; Dr. Frederick H. Rollins, St. Charles, is a candidate for the state senate.

New Hospital in Midway District.—The Northwestern Hospital Association is constructing a $750,000 hospital on an eight acre tract in the Midway District between St. Paul and Minneapolis which, it is expected, will be ready for occupancy, August 1; construction work started last July. The building is fireproof and in other respects of the most modern type of construction. The Northwestern Baptist Hospital Association, which began its work twenty-one years ago, when the Mounds Park Sanatorium, St. Paul, was opened, now cares for about 3,500 patients annually and its free service to the sick has increased in proportion to its growth.

Society News.—The Minnesota Academy of Ophthalmology and Oto-Laryngology elected Dr. John L. Shellman, St. Paul, president, May 14; Drs. Walter E. Camp, Minneapolis, and Frank N. Knapp, Duluth, vice presidents, and Dr. John H. Morse, Minneapolis, secretary-treasurer.——Dr. George E. Fahr, Minneapolis, was elected president of the Minnesota Pathological Society, May 11; Dr. Wallace H. Cole, St. Paul, vice president, and Dr. Elexious T. Bell, Minneapolis, secretary-treasurer.——Drs. William J. and Charles H. Mayo, Rochester, addressed the annual meeting of the American Surgical Association, Detroit, May 24-26, on "Rehabilitation of the Surgical Patient Through Biochemical Methods" and "The Gallbladder of 1926," respectively.

NEW HAMPSHIRE

State Medical Election.—At the one hundred and thirty-fifth annual meeting of the New Hampshire State Medical Society, Concord, May 26, Dr. David W. Parker, Manchester, was elected president; Dr. Emery M. Fitch, Claremont, vice president; Dr. Dennis E. Sullivan, Concord, secretary-treasurer (reelected), and Dr. Joseph J. Cobb, Berlin, speaker of the house of delegates. Dr. Thomas W. Luce, Portsmouth, is the retiring president. The next meeting will be held at Portsmouth in 1927.

NEW JERSEY

Hospital News.—Citizens of Princeton launched a campaign, June 1, to raise $600,000 for a new Princeton hospital, the capacity of which will be fifty-six beds. The first day of the drive for a community hospital netted more than $140,000; the largest donation was $37,500, by George A. Armour and family, for an operating room; Mr. and Mrs. Gerard B. Lambert gave $24,000; two children contributed all they had in the bank, a total of twenty-eight cents; an anonymous gift of $6,000 was made in memory of Isabella McCosh, wife of a former president of the university, in whose honor the university infirmary is named.——The cornerstone of the new $300,000 Dover General Hospital was laid, April 25.——The Presbyterian Hospital, Newark, is conducting a campaign for $450,000 for a new building.——The Dr. E. C. Hazard Hospital, Long Branch, is building a $75,000 addition.

Illegal Practitioners in Court.—The following persons have recently been brought into court charged with practicing medicine, chiropractic or midwifery without a license:

Albert H. Smith, a druggist, Bradley Beach (fined).

J. Harry Hayes, a druggist, Asbury Park (fined).

Ferdinand Boutel, formerly of Elizabeth (fined).

James C. Van Middlesworth, Elizabeth (fined).

Lillian Carter, Camden (committed to jail for twenty days).

George Schaefel, Oaklyn (fined).

Mary Jergufski-Hammon, a midwife, Trenton (fined).

Anna Falcone, a midwife, Passaic (fined), for practicing midwifery without a license.

Carmela Suco, Passaic, committed to jail for sixty days.

Henry P. Livesey, Arlington, a licensed chiropractor who was practicing electrotherapeutics in connection with the practice of chiropractic (fined).

Margaret Lehman, Trenton (fined).

Edward E. Garlits, proprietor of a health food store, Trenton (fined).

Herman North, Bloomfield, a druggist (fined).

Anna Antolik, Whippany, an unlicensed midwife, and Anna Kudelka, Boonton, an unlicensed midwife, and Adolph Schror, Rockaway Valley, were each tried for practicing medicine without a license, and judgment entered for the penalty and costs, but each filed notice of an appeal.

NEW YORK

Control of Venereal Disease.—The director, division of social hygiene, state department of health, summarizes the activities in New York, exclusive of New York City, for the control of venereal disease from 1919 to 1925. He says, there were 4,383 lectures attended by 509,869 persons, and 3,241,576 pamphlets distributed, and 32,089 patients who were unable to pay for medical attention treated at the free clinics. There were 28,777 cases of syphilis in New York last year. There are ninety-one laboratories approved for the examination of "smears," sixty-seven laboratories approved for dark field examinations for syphilis, and thirty-eight laboratories approved for performing the Wassermann test. There were examined during this period (1919-1925) 174,876 smears for gonococci, and 1,374,460 Wassermann tests made. The physicians, the public and the state are cooperating to control these diseases.

Society News.—Dr. William H. Ross, Brentwood, addressed the semiannual meeting of the Suffolk County Medical Society, Patchogue, May 18, on "The Influence of Diet in Chronic Arthritis," and Dr. Blake F. Donaldson, New York, held a clinic on nephritis.——Dr. Frederick C. Conway addressed the Medical Society of the County of Albany, June 8, on "Case of Pericarditis with Effusion"; Dr. Stanley E. Alderson, on "Case of Perforated Duodenal Ulcer"; Dr. Otto A. Faust, on "Case of Lung Abscess"; Dr. E. Martin Freund, on "Two Cases of Bronchial Asthma"; and Dr. John E. Heslin, on "Hematuria in the Male." The members of this society are invited to a clam-bake, June 24, given by the Berkshire District Medical Society at Pontoosac Lake, Pittsfield, Mass. ($5 per ticket). Ladies also are invited. There will be golfing and tennis.——At the first annual meeting of the Genesee County Medical Association, June 4, the guest of honor and chairman was Dr. Clement R. Jones, Pittsburgh, treasurer of the American College of Physicians; Dr. John Phillips, Cleveland, addressed the society on "Abdominal Conditions Which Are Essentially Nonsurgical"; Dr. Charles Gordon Heyd, New York, on "Differential Diagnosis of Surgical Conditions of the Upper Abdomen," and Dr. Ernst A. Pohle, University of Michigan School of Medicine, Ann Arbor, on "Therapeutic Use of Radiation with Special Consideration of Ultraviolet Therapy." Following the scientific meeting, there were golfing, tennis, hiking and swimming, and in the evening a dinner dance.

New York City

Society News.—About 100 physicians and guests attended the annual dinner dance of the Three Hundred and Second Medical Regiment at the Hotel Bossert, May 22.——The trustees of the New York Academy of Medicine and members of the public health committee gave a testimonial dinner to Dr. Charles L. Dana on the occasion of the fifteenth anniversary of the formation of the committee of which Dr. Dana is chairman.

Travel Study Club.—The Travel Study Club of American Physicians left for an eight weeks tour of Europe, June 12, to visit Norway, Sweden, Denmark, Germany, Switzerland, France and England. Ten days will be spent in Germany at Cologne, Dusseldorf, Neuenahr, Wiesbaden, Heidelberg and Baden-Baden, where special receptions and banquets will be given by the Kur-Administrations and their German colleagues. Dr. Louis L. Seaman is president of the club, and Dr. Richard Kovacs, secretary-treasurer.

Committee on Maternal Health.—Organized in 1923 to make a scientific investigation of contraception, sterilization and problems of sterility and fertility from a medical and public health point of view, the Committee on Material Health has undertaken a clinical study of contraception, in which eight hospitals are cooperating. The clinical work aims (1) to provide medical advice for women who need advice about contraception to cure or prevent disease as permitted under the state [illegible] (2) to collect evidence as to conditions under which [illegible] for or against pregnancy should be given and, [illegible] collect histories of patients who use contraceptive methods under medical supervision. The committee, [illegible] offers an honorarium in order to secure complete histories, aims to keep patients under supervision for at least one year, and strictly limits itself to advising patients who present medical indications. It is expected that the study of these histories will help answer, scientifically, such questions as "What are the physiologic and psychologic effects of contraception on the individual?" "What are the effects of contraception on subsequent fertility?" and "What are the relative values of contraceptives as to reliability, simplicity and harmlessness?" The committee also aims to promote research on problems of sterility and fertility. Reports will be issued to the medical profession from time to time; a great deal of opinion on these questions through interviews in Europe and America, has been collected, but the opinions differ widely, and an unbiased investigation is being made of the facts. The medical members of the committee are Drs. Samuel W. Lambert, chairman; Robert L. Dickinson, secretary; Haven Emerson, Robert T. Frank, Frederick C. Holden, George W. Kosmak, James Pedersen and William F. Snow; the office is at 370 Seventh Avenue.

NORTH CAROLINA

Hospital News.—More than $80,000 had been obtained at last report in the campaign to raise $100,000 for the erection of a hospital for negroes at Greenboro.——Haywood County approved, June 5, a bond issue of $100,000 to establish a county hospital in the county seat, Waynesville.

Initial Payment by Duke Foundation.—The Duke Endowment Headquarters at Charlotte mailed checks recently to hospitals not operated for private gain and to orphanages in North and South Carolina, amounting to $267,912.95. This was the initial instalment of payments (THE JOURNAL, Dec. 20, 1924, p. 2027).

Personal.—Dr. George Fletcher Reeves, Winston-Salem, has been elected full-time health officer for Nash County, and will take up his duties, July 1.——Dr. Vincent W. Archer, formerly of Black Mountain, who has been elected professor of roentgenology in the Medical School of the University of Virginia, will assume charge of that department at the opening of the fall term.

Four Months on the Road Gang.—About twenty-five negroes were witnesses in the trial of William Lowery, a Croatan Indian, in the superior court at Clinton, May 13, who was charged, it is reported, with practicing medicine without a license. Lowery is said to have traveled about the community selling medicines prepared by himself and offering to cure various ailments for a certain sum of money. Judge Bond sentenced the "doctor" to serve four months on the county roads.

OHIO

Society News.—Drs. Preston M. Hickey, Aldred S. Warthin and Frank N. Wilson of the University of Michigan Medical School, Ann Arbor, held "A Pathologic and Roentgenologic Conference on Proved Cases" before the Academy of Medicine of Toledo and Lucas County, Toledo, June 4.——Dr. Karl D. Figley, Toledo, addressed the Sandusky County Medical Society, Fremont, May 20, on "Periodic Health Examinations."——The Montgomery County Medical Society was the guest, on the occasion of its annual meeting, of Dr. Charles B. Rogers at the Orchard Springs Sanatorium, near Dayton; Dr. Max Ballin, Detroit, addressed the society on "Abdominal Diagnosis and Surgery."——Dr. Henry Kennon Dunham of the University of Cincinnati College of Medicine addressed the Columbiana County Medical Society, East Liverpool, June 10, on "Importance of Exact Diagnosis and Classification of Lung Lesions."

Personal.—Dr. Charles H. Pelton has resigned as superintendent of the Memorial Hospital, Elyria, and Mr. John Mannix, of Mount Sinai Hospital, Cleveland, has been appointed superintendent.——Dr. Eli R. Crew, superintendent, Miami Valley Hospital, Dayton, was chosen president elect of the Ohio Hospital Association at the recent annual meeting in Columbus.——Mr. A. G. Stouder, Troy, recently gave $200,000 to that city for the erection of a memorial hospital to be known as the Stouder Memorial.——A dinner in honor of Dr. John N. Lenker, Cleveland, was given, May 21, by the staff and trustees of St. Luke's Hospital; Dr. Lenker, who has been associated with this hospital for twenty-five years, had just returned from an extended trip around the world.——Dr. Benjamin A. S. Stephenson, Columbus, has been elected health officer of Hocking County and the city of Logan, to succeed Dr. William G. Rhoten, who has accepted a position as health officer of Wayne County.——Dr. William H. Eastman, Fredericktown, was elected president of the Knox County board of health at the annual business meeting, June 1.

PENNSYLVANIA

Mental Clinics.—Regular mental clinics were recently established in Clearfield and Venango counties, and occasional clinics in the public schools of Pike County and at the Brookville Red Cross. There are now forty-six regular mental clinics being conducted under the auspices of the bureau of mental health of the state department of welfare, and five occasional mental clinics.

Society News.—Dr. John B. Deaver, Philadelphia, addressed the Newcastle County Medical Society, May 18, on "Peritonitis."——Dr. James M. Anders addressed a joint meeting of the Montgomery County Medical Society and the local tuberculosis society, Norristown, June 2, on "Disease Prevention, with Especial Reference to Tuberculosis."——Dr. Thomas M. Mabon addressed the Allegheny County Medical Society, Pittsburgh, June 15, on "Myxedema" (lantern slides); Dr. Harvey E. Thorpe, "Slit Lamp Microscopy of the Living Eye," and Dr. Isaac L. Ohlman, "A Nonboiling Method of Sterilizing Syringes for Intravenous Work."

Philadelphia

Hospital News.—The $1,000,000 drive to enlarge the Bryn Mawr Hospital was oversubscribed, the grand total being $1,275,984, which does not include thousands of dollars given for memorials.

Dr. Sweet Goes to Cornell.—Dr. Joshua E. Sweet, who has conducted the department of surgical research at the University of Pennsylvania for twenty years, has accepted the chair of surgical research at Cornell University Medical College, New York; a dinner was given, June 5, in honor of Dr. Sweet; Dr. George M. Dorrance presided, and Drs. William Pepper, George W. Norris, Edward B. Krumbhaar and De Witt C. Guthrie were among the speakers.

Health Talks for the Public.—Under the auspices of the Philadelphia County Medical Society, addresses were delivered in the auditorium of the society's new home, Twenty-first and Spruce streets, by Dr. Wilmer Krusen, director of health, June 8, on "Health Problems of a Great City," by Dr. Frank C. Hammond, dean, Temple University School of Medicine; June 15, on "The Social Evil" (for men only), and by Dr. Harriet Hartley, June 15, on "Some Phases of Hygiene" (for women only).

Woman's Medical College.—At the seventy-fourth annual commencement of the Woman's Medical College of Pennsylvania, June 9, twenty-nine women received the degree of doctor of medicine; the commencement address was given by Dr. John A. Lichty, superintendent, Clifton Springs Sanatorium, Clifton Springs, New York. Following the commencement, a bronze tablet was unveiled in honor of Dr. Anna S. Kugler, '79, and Dr. Lydia Woerner, '99, both of whom spent many years in India as medical missionaries. The Lutheran Women's League of Philadelphia and vicinity presented the tablet together with two scholarships of $5,000 each, to provide for the training of medical missionaries. Ten of this year's graduating class expect to serve as medical missionaries in widely scattered foreign posts. During the annual meeting of the alumni association, June 10-11, there were scientific demonstrations and clinics, a banquet at the Bellevue-Stratford Hotel, business meetings, luncheons, and a visit to the proposed site of the greater Woman's Medical College, Henry Street and Abbottsford Road, Falls of Schuylkill.

RHODE ISLAND

Hospital News.—The Miriam Hospital, Providence, which was opened to the public last November, has opened an outpatient department with clinics in internal medicine, gynecology, surgery, diabetes, eye, ear, nose and throat and prenatal work.

State Medical Election.—At the one hundred and fifteenth annual meeting of the Rhode Island Medical Society, Providence, June 3, Dr. Herbert G. Partridge, Providence, was elected president; Drs. Norman M. MacLeod, Newport, and Arthur H. Harrington, Howard, vice presidents; Dr. Jesse E. Mowry, treasurer, and Dr. James W. Leech, 369 Broad Street, Providence, secretary. The principal speaker at the annual banquet was Charles U. Clark, Ph.D., Quebec, Canada. Dr. Charles L. Scudder, Harvard University Medical School, Boston, spoke at the morning session on "Operative Treatment of Fractures," and Dr. Howard E. Blanchard, Providence, on "Corrective Rhinoplasty," illustrated by moving pictures, through the courtesy of Dr. Joseph Eastman Sheehan, New York; at the afternoon session there was a symposium on "Cancer" by members of the staff of Memorial Hospital, New York.

TENNESSEE

Medical School Adopts Quarter System.—It is reported that the trustees of the University of Tennessee have adopted the quarter system whereby by continuous study the two premedical and four medical years of work can be completed in as short time as four and a half years. Under this system, any three quarters will be considered the equivalent of one college year.

Health at Nashville.—Telegraphic reports to the U. S. Department of Commerce from sixty-four cities with a total population of about 29,000,000, for the week ending May 22, shows the highest mortality rate for Nashville (21.3), and a mortality rate for the group of cities of 13.3. In the corresponding week last year the mortality rate for Nashville was 18.4, and for the group of cities, 12.9. The annual rate for the sixty-four cities for the twenty-one weeks of 1926 was 15.5, while for the corresponding period last year it was 14.2.

Society News.—At the sixty-third semiannual meeting of the Middle Tennessee Medical Association, Springfield, May 21, Dr. Thomas D. McKinney, Nashville, was elected president; Dr. William W. Porter, Springfield, vice president, and Dr. Sam P. Bailey, Nashville, secretary-treasurer, reelected. The next meeting will be held at Dickson.——At the thirty-fifth annual meeting of the West Tennessee Medical and Surgical Association, Dr. Richard M. Little, Martin, was elected president; Dr. William C. Duckworth, Jackson, vice president; Dr. Isaac A. McSwain, Paris, secretary-treasurer, reelected, and Dr. George R. McSwain, Paris, assistant secretary. The next annual meeting will be at Dyersburg.

WASHINGTON

Hospital News.—The Oakhurst Tuberculosis Sanatorium at Elma will construct a $50,000 hospital for male patients.——Brig. Gen. Frank T. Hines has ordered the construction of an infirmary building for the tuberculous patients at the Veterans' Bureau Hospital, Walla Walla.

Personal.—Dr. Edward J. Lawrence, Spokane, has been elected president of the University Club of that city.——Dr. and Mrs. George S. Allison, Spokane, recently celebrated their golden wedding anniversary.——Dr. Frances R. McLoughlin, Seattle, has been appointed, by the governor, to the state institutional board of health.

Osteopaths Want to Prescribe Narcotics.—Having been refused registration under the Harrison Narcotic Act, by the collector of internal revenue, certain osteopaths of the state petitioned for, and received, a writ of mandamus directing the internal revenue collector to register one W. E. Waldo, Seattle, before June 21, or show cause in court for failing to comply. The state law, known as the Beeler Act, prohibits the possession, sale and use of narcotic drugs, except by "physicians, dentists, surgeons and veterinarians," and, in the opinion of the assistant state attorney general, osteopaths are not included in the excepted classification. The osteopaths have not only been refused registration under the state law, but have been called on to turn in at once all narcotic drugs they may have in their possession.

WEST VIRGINIA

Personal.—Drs. Robert J. Reed and Frank LeMoyne Hupp, both of Wheeling, received the honorary degree of doctor of science from Washington and Jefferson College, Washington, Pa., June 16.——Dr. Garner Scullard, Pittsburgh, has been appointed pathologist at the Ohio Valley General Hospital, Wheeling.

State Medical Election.—At the recent annual meeting of the state medical association, Morgantown, Dr. Chester R. Ogden, Clarksburg, was elected president; Drs. Charles B. Wylie, Morgantown, Claude A. Frazier, Powellton, and Edmund L. Armbrecht, Wheeling, vice presidents; Dr. Thomas Maxfield Barber, Charleston, treasurer, and Mr. Sterrett O. Neale, Charleston, executive secretary. The next annual meeting will be in White Sulphur Springs.

Society News.—Dr. Hanson S. Ogilvie, Charleston, recently addressed the Mercer County Medical Society, Bluefield, on "Simple Diagnostic and Therapeutic Principles in Neurology."——Dr. Charles H. Clovis, Wheeling, has been elected president of the Ohio County Medical Society, and Dr. John W. Gilmore, Wheeling, vice president; Dr. Walter D. Wise, Baltimore, recently addressed the society on "A Plea for Earlier Operation in Surgical Conditions of the Biliary Tract."——The Upshur County Medical Society was reorganized in May, and Dr. Everett Walker, Adrian, was reelected president; Dr. Lowry W. Page, Buckhannon, vice president, and Dr. Leonard W. Deeds, Buckhannon, secretary.

WISCONSIN

Personal.—An award of $25,000 has been approved by the Mixed Claims Commission, representing the United States and Germany, to the widow of Dr. Edmund F. Woods, Janesville; Dr. Woods lost his life when the *Arabic* was sunk by a German submarine off the coast of Ireland, Aug. 19, 1915.

University News.—Dr. Arno B. Luckhardt, professor of physiology, University of Chicago, addressed the University of Wisconsin Medical Society, recently, on "Ethylene-Oxygen and Acetylene-Oxygen Anesthesia," and the medical students of the University of Wisconsin on "The Physiology of the Parathyroid Gland."

Society News.—Dr. Louis M. Warfield, Milwaukee, addressed the Dodge County Medical Society, Beaver Dam, recently, on "Diseases of the Heart."—Dr. Charles Eugene Riggs and Dr. William H. Hengstler, St. Paul, addressed the Douglas County Medical Society, Superior, May 5, on "Sleeping Sickness."——Dr. Erwin R. Schmidt, professor of surgery, University of Wisconsin Medical School, Madison, addressed the Sauk County Medical Society, May 19, on "The Surgical Aspect of the Acute Abdomen in Babies and Young Children"; and Dr. Roscoe L. McIntosh, University of Wisconsin Medical School, addressed the society on "Treatment of Diseases of the Skin."——Dr. Herman E. Wolf, La Crosse, was elected president of the Seventh Councilor District Society, and Dr. Dean S. Smith, La Crosse, secretary, at the meeting at Sparta.——The Ninth Councilor District Society met, May 13, at Stevens Point; Dr. Arthur J. Patek, Milwaukee, held a clinic in the afternoon, and the evening was given over to a symposium on periodic health examinations, which was followed by a general discussion. Dr. Donald Waters, Wisconsin Rapids, was elected president of the society, and Dr. Joseph F. Smith, Wausau, secretary, reelected.——Twenty-three physicians of Fond du Lac donated their services recently to make thorough physical examinations of more than 600 children in the first grades of the public schools.

GENERAL

Is Cancer Increasing?—There were 99,138 deaths recorded in 1924 in the registration area of the United States as directly due to cancer, according to the Public Health Service. These figures are based on returns from the registration area, which comprises 88.4 per cent of the total population. On the basis of these reports, the rate of deaths from cancer per hundred thousand of population was 92. In 1923, the rate was 89.4, while in 1900 the reports revealed the rate to be 63.

Automobile Fatalities.—The department of commerce announces that reports on automobile fatalities from seventy-nine large cities in this country for the four week period ending May 22 shows that the total number of persons killed was 487, as contrasted with 426 for the corresponding four weeks in 1925. Eight of the cities reporting had no automobile fatalities during this period this year, while for the corresponding period last year eleven cities had no automobile fatalities. New Bedford, Mass., it is said, has a "clean sheet" for the last twenty weeks.

Prizes for Improvement in Medical Equipment.—The International Committee of the Red Cross has provided, in accordance with a decision of the Twelfth International Red Cross Conference, 100,000 Swiss francs for prizes and competitions in an effort to improve and standardize some articles of medical equipment. The competitions will apply to stretchers, devices for suspending stretchers, individual packages for dressings, cards for wounded men, and identification tags; they will take place at Geneva this fall, but the objects entered in the competitions must reach the International Committee of the Red Cross, 1, Promenade du Pin, Geneva, before August 1, and must be marked "material intended for the institute for international examination of medical equipment," so they will be exempt from custom duties. The international committee will be grateful to receive from persons interested in perfecting medical equipment, supplementary funds to enable it to increase the value of the prizes to be given. An international technical commission will act as the jury of awards.

Pacific Northwest Medical Association.—The annual meeting of this association will be at Spokane, Wash., July 1-3, at the Davenport Hotel, the meeting place having been changed from Glacier Park because the hotels could not promise to provide sufficient facilities. The Pacific Northwest Orological Society and the Pacific Northwest Orthopedic Society will meet jointly with the medical association. Among many prominent speakers will be Dr. George Dock, Pasadena, Calif., whose subjects will be the anemias and the nephropathies and a clinic; Dr. John Whitridge Williams, Johns Hopkins University School of Medicine, Baltimore, whose several subjects relate to obstetrics; Dr. Arthur Steindler, State University of Iowa College of Medicine, Iowa City, whose subjects relate to orthopedic surgery; Dr. George W. Holmes, roentgenologist, Massachusetts General Hospital, Boston; Dr. Harry L. Parker, Mayo Clinic, Rochester, Minn., "Diagnosis of Suppurative Diseases of the Central Nervous System" and "Clinical Signs and Symptoms of Neuritis"; Dr. Howard Lilienthal of Cornell University Medical College, New York, surgical treatment of pulmonary tuberculosis and of nontuberculous suppuration; Dr. Alfred W. Adson, neurologist, Mayo Clinic, Rochester, Minn.; Dr. George H. Semken, surgeon in chief, New York Skin and Cancer Hospital; Dr. Albert Keidel, Johns Hopkins University School of Medicine, Baltimore; Dr. E. H. Mason, McGill University Faculty of Medicine, Montreal, and Dr. Hans Lisser, of the University of California Medical School.

Pan-American Red Cross Conference.—About 250 foreign guests from more than thirty countries, representing national and international medical and nursing societies, met with delegates from national Red Cross societies in the Western Hemisphere at the second Pan-American Red Cross Conference, Washington, D. C., May 25-June 5. President Coolidge, as head of the American Red Cross, welcomed the delegates. The conference was sponsored by the League of Red Cross Societies, representing fifty-four member nations. The first Pan-American Red Cross Conference was held at Buenos Aires in 1923; the third will be held at Rio de Janeiro, about 1930. With the business of the conference, there were interspersed official dinners, receptions, luncheons and excursions in honor of guests, a visit to Mount Vernon to place a wreath, a gift of the conference, on the tomb of George Washington, and to Warrenton, Va., to the estate of the Hon. Oscar T. Crosby, former assistant secretary of the U. S. Treasury. Among the resolutions adopted by the conference were that: (1) child welfare is a proper activity for the Red Cross; (2) it should participate in the prevention of blindness, as well as in the creation of working homes for the blind; (3) Red Cross societies should take such action as will enable teachers to advise medical examination of every child who seems to suffer from an infection of the tonsils; (4) Red Cross societies should take steps for governments to establish (or to do so themselves) special health courses in which special teachers would be trained in the teaching of hygiene in the public schools; (5) the Red Cross societies should undertake the teaching of health principles with a view to develop a public conscience in the great medical and social problems, and (6) Red Cross societies should take steps to introduce in local newspapers, daily, weekly or biweekly service, giving practical information and advice on health matters.

Activities of Rockefeller Foundation in 1925.—Through its departmental agencies (the International Health Board, the China Medical Board, the Division of Medical Education, and the Division of Studies), the Rockefeller Foundation spent $9,113,730 during 1925. George E. Vincent, Ph.D., the president, states in his annual review that the foundation engaged in the following activities:

(1) Aided the governments of eighteen countries to combat hookworm disease; (2) gave funds to the budgets of organized rural health services in 220 counties in twenty-six American states and in eighteen districts in Brazil, Poland, Czechoslovakia, Austria and France; (3) took precautionary measures against yellow fever in Salvador, Guatemala, Nicaragua and Honduras; (4) continued to work with Brazil in freeing its northern coast from this disease; (5) sent a yellow fever commission to the West Coast of Africa; (6) helped to show the possibilities of malaria control in twelve American states, and in Brazil, Argentina and Italy; (7) shared in the development of professional training of public health officers at Harvard University and the University of Toronto and in schools and institutes in London, Copenhagen, Prague, Warsaw, Belgrade, Zagreb, Budapest, Trinidad and São Paulo; (8) contributed to the progress of medical education at Cambridge, Edinburgh, Copenhagen, Brussels, Utrecht, Strasbourg, Beirut, Singapore, Bangkok, São Paulo and Montreal; (9) provided emergency aid in the form of literature and laboratory supplies for 112 medical centers in Europe; (10) maintained a modern medical school and teaching hospital in Peking with 164 students and fifty-five teachers; (11) aided two other medical schools and nineteen hospitals in China; (12) helped to improve the teaching of physics, chemistry and biology in three Chinese and seven foreign institutions in China and in the government university of Siam; (13) supported nurse training courses in Peking Union Medical College, Yale University, Vanderbilt University and the George Peabody College for Teachers, and contributed to nursing education and service in Brazil, France, Jugoslavia and Poland; (14) provided current funds for an Institute of Biological Research in the Johns Hopkins University; (15) assisted departments at Yale and Iowa State universities engaged in biologic and mental research, and aided the Marine Biological Station at Pacific Grove, Calif.; (16) provided, directly or indirectly, fellowships for 842 men and women from forty-four different countries, and financed the travel of fifty other persons either in commissions or as visiting officials and professors; (17) contributed to the League of Nations international study tours or interchanges for 128 health officers from fifty-eight countries; (18) continued to aid the league's information service on communicable diseases; (19) made surveys of health conditions, medical education, nursing, biology and anthropology in thirty-five countries; (20) lent staff members as advisers and made minor gifts to many governments and institutions; (21) assisted mental hygiene projects both in the United States and Canada, demonstrations in dispensary development in New York City, and other undertakings in public health, medical education and allied fields.

Society News.—At the recent annual meeting of the American Pediatric Society, Dr. Isaac A. Abt, Chicago, was elected president; Dr. Royal S. Haynes, New York, vice president; Dr. Clifford G. Grulee, Chicago, editor, and Dr. Howard C. Carpenter, 1805 Spruce Street, Philadelphia, secretary-treasurer.—The American Otological Society has elected Dr. Arthur B. Duel, New York, president for the ensuing year; Dr. Max A. Goldstein, St. Louis, vice president, and Dr. David Harold Walker, 390 Commonwealth Avenue, Boston, secretary-treasurer.——At the annual meeting of the American Laryngological Association, June 3-5, Dr. Chevalier Q. Jackson, Philadelphia, was elected president; Drs. Lewis A. Coffin, New York, and William V. Mullin, Cleveland, vice presidents; Dr. George Fetterolf, Philadelphia, treasurer, and Dr. George M. Coates, 1721 Pine Street, Philadelphia, secretary.——The American Urological Association elected Dr. John R. Caulk, St. Louis, president at the annual meeting, May 17-19; Dr. Richard F. O'Neil, Boston, president-elect; Dr. Homer G. Hamer, Indianapolis, secretary, and Dr. James B. Cross, Buffalo, treasurer.——Dr. Burt R. Shurly, Detroit, was elected president of the American Laryngological, Rhinological and Otological Society, at the meeting, Montreal, May 31-June 2; Drs. Hubert Arrowsmith, Brooklyn, John J. Shea, Memphis, Harry W. Lyman, St. Louis, William P. Wherry, Omaha, and Frank B. Kistner, Portland, vice presidents; Dr. Ewing W. Day, Pittsburgh, treasurer; Dr. George L. Richards, Fall River, Mass., editor, and Dr. Robert L. Loughran, 145 West Fifty-Eighth Street, New York, secretary.——At the meeting of the American Neurological Association, June 1-3, Dr. Peter Bassoe, Chicago, was elected president; Drs. Ernest Sachs, St. Louis, and James B. Ayer, Boston, vice presidents; Dr. Henry Alsop Riley, 870 Madison Avenue, New York, secretary-treasurer, and Dr. Clarence A. Patten, Philadelphia, assistant secretary.——Dr. Carroll L. Smith, Spokane, was recently elected president of the Pacific Coast Oto-Ophthalmological Society; Dr. William J. Mellinger, Santa Barbara, Calif., and Dr. Frank A. Burton, San Diego, vice presidents, and Dr. Walter F. Hoffman, Seattle, secretary-treasurer.——At the annual meeting of the National Association for the Study of Epilepsy, New York, June 7-8, Dr. George Kirby Collier, Rochester, N. Y., was elected president; Drs. Dan S. Renner, Skillman, N. J., and Thomas B. Bass, Abilene, Texas, vice presidents, and Dr. Arthur L. Shaw, 108 B. The Albiston, Utica, N. Y., secretary-treasurer. The next meeting will be at Cincinnati.——Dr. John Ruhräh, Baltimore, was elected president of the American Medical Library Association at the annual meeting in Ann Arbor, June 8-9; Dr. Harvey Cushing, Boston, vice president; Miss Sue Biethan, Ann Arbor, secretary, and Miss Metta Loomis, Chicago, treasurer.——The American Bronchoscopic Society elected Dr. Daniel Crosby Green, Boston, president; Dr. Sidney Yankauer, New York, vice president, and Dr. Henry B. Orton, 24 Commerce Street, Newark, N. J., secretary-treasurer at the annual meeting, May 29.——The American Psychopathological Association, at its annual meeting, June 11, elected Dr. Sanger Brown, 2d, New York, president; Drs. Ross M. Chapman, Towson, Md., and Edward J. Kempf, New York, vice presidents; Dr. William C. A. Garvin, Binghamton, N. Y., treasurer, and Dr. Martin W. Peck, Boston Psychopathic Hospital, Boston, secretary.

FOREIGN

Personal.—Prof. A. J. Clark has been chosen to succeed the late Prof. Arthur R. Cushny in the chair of materia medica and pharmacology at the University of Edinburgh.

Clinical Course in English.—The Faculty of Medicine of Paris offers a complementary, postgraduate course in mental diseases and diseases of the brain at the Neuropsychiatric Clinic, June 12 to July 12, under the direction of Prof. Henri Claude, in which there will be complementary explanations in English and Spanish. Applications should be made to the chief of clinic, Dr. Targowla, 1, Rue Cabanis, Paris.

Photographs in Court Prohibited.—The *Lancet*, May 29, notes that after June 1 physicians in England will be protected from a form of publicity which they sometimes encounter, but seldom enjoy in that country. On that day, a law becomes effective, which makes it an offense to photograph, in any court, any person who is a judge, a juror, a witness or one of the parties in the case. Any other kind of portraiture or sketching attempted in court with a view to publication is also prohibited, and photographing is deemed to occur in court if it takes place anywhere within the court buildings, or while the victim is entering or leaving the court room, or the precinct of the building. Violation of the new law is punishable, summarily, by a fine not to exceed £50.

Deaths in Other Countries

Stephen Paget, consulting aural surgeon, Middlesex Hospital, vice chairman, Research Defense Society, author of "Memoirs and Letters of Sir James Paget," "The Life of John Hunter" and of "Ambroise Paré and His Times," and many other volumes, May 8, aged 71.——**Ernest Septimus Reynolds**, emeritus professor of clinical medicine, University of Manchester, England, May 22, aged 65.

CORRECTION

Necropsy Percentage.—In the table in Dr. Henry A. Christian's article on "Selecting a Hospital for the Internship" (THE JOURNAL, May 15, p. 1500), the necropsy percentage for Johns Hopkins Hospital, Baltimore, should be 74.5 per cent instead of 84 + per cent.

Government Services

Navy Personals

Lieut. William Moore and Lieut., junior grade, George C. Main, have resigned from the medical corps of the navy.——Comdr. Abraham H. Allen has been ordered to duty on the U. S. S. *Mercy*.——Lieut. Comdr. Carl A. Broaddus, on completion of his course of instruction at the New York Post-Graduate Medical School and Hospital, will proceed to the naval hospital, League Island, Pa., for duty.——Lieutenants, junior grade, Sobisca S. Hall, naval hospital, New York, and Radford Brown, U. S. S. *Elcano*, have tendered their resignations from the medical corps of the navy.

Army School of Nursing

The graduating exercises of the Army School of Nursing were held in the Formal Garden, Army Medical Center, Washington, D. C., June 4; the Surgeon General, Major Gen. Merritte W. Ireland, presided and Mrs. Florence P. Kahn gave the address; Brig. Gen. James M. Kennedy, commanding officer, Army Medical Center, presented the diplomas, and Mrs. Henry R. Rea the Rea Medal, which was awarded to Barbarba Channing Miller of Vermont. There were forty-six graduates in the class.

U. S. Public Health Service

Surg. Roy P. Sandidge has been relieved from duty at Honolulu and assigned to the U. S. Quarantine Station, Rosebank, N. Y.——Asst. Surg. Lucius F. Badger, Jr., has been relieved from duty at Angel Island, Calif., and assigned to the U. S. Quarantine Station, Honolulu.——Surg. Ernest A. Sweet has been relieved from duty at Honolulu and directed to assume charge of the U. S. Quarantine Station at Fort Monroe, Va.——Surg. John W. Tappan has been relieved from duty at El Paso, Texas, and assigned to Fort Stanton, N. M.——Surg. J. G. Wilson has been relieved from duty at Los Angeles and directed to assume charge of service activities at El Paso.——P. A. Surg. Lieuen M. Rogers has been relieved from duty at Fort Stanton and assigned to duty at the hygienic laboratories, Washington, D. C.——Surg. Walter C. Teufel has been relieved from duty at Miami, Fla., and assigned to duty at Dublin, Ireland.——Surg. Lewis R. Thompson has been directed to proceed from Washington, D. C., to New York and return in connection with studies of posture and dust which the service is conducting.——Asst. Surg. Henry A. Rasmussen has been relieved from duty at Fort Stanton, N. M., and assigned to Ellis Island, New York.

Graduation at Field Service School

The U. S. Army Medical Field Service School, Carlisle Barracks, Pa., graduated a class of fifty-five members, June 3, thirty-two of whom were members of the medical corps, thirteen of the veterinary corps, eight of the dental corps, and two from the Cuban army. Lieut. Col. Charles R. Reynolds presented the diplomas; Col. Harlow Brooks, medical reserve corps, professor of clinical medicine, University and Bellevue Hospital Medical College, New York, gave the address. The Skinner medal was awarded to Capt. Joseph I. Martin, U. S. Army, Medical Corps, he having attained the highest general average. Following the exercises, there was a review of the troops in honor of the Surgeon General and the visiting officers, and following this, a reception was tendered General and Mrs. Ireland and Colonel and Mrs. Brooks at the home of Colonel Reynolds.

Captured Whisky for Patients

The Surgeon General of the army has accepted a proposal made by the federal prohibition agent at Tampa, Fla., to turn over to the medical department of the army forty barrels of whisky which have been captured off the Florida coast. The state prohibition officer states that five years ago forty barrels of whisky, made in this country prior to the passage of the prohibition law but shipped out of the country when the law went into effect, were captured off the coast of Florida when an attempt was made, illegally, to return it to the United States. The federal court issued an order that the whisky be confiscated. The prohibition agent, however, secured a modification of the order for the purpose of having this supply turned over to hospitals of the army and navy. The liquor is at present stored at Key West, Fla.

Protection Against Lead Paint Poisoning

A bill to make better provision for the protection against lead poisoning of persons employed in painting buildings is to be introduced by the government. It provides that the secretary of state may make regulations for preventing danger from the use of lead paint to persons employed in or in connection with the painting of buildings, and in particular for prohibiting the use of any lead compound except in the form of paste or of paint ready for use; for the prevention of danger arising from the application of lead paint in the form of spray; for the prevention so far as practicable of danger arising from dust caused by dry rubbing down and scraping; for providing for the medical examination of persons employed in or in connection with painting with lead paint, and for the suspension from such employment of persons whose health is or appears likely to be injuriously affected thereby; for securing facilities for washing during and on cessation of work to persons employed in painting; for the use of protective clothing by persons so employed; for preventing clothes left off during work from being soiled by paint, and for the distribution to persons so employed of instructions with regard to hygienic precautions to be taken. The bill prohibits the employment of any woman or young person in painting any part of a building with lead paint. But this does not apply to the employment of persons employed as apprentices in the painting trade under arrangements approved by an order of the secretary of state made after consultation with the organizations, if any, representative of the employers and workers in the trade; or women or young persons in such special decorative or other work (not being work of an industrial character) as may be excluded from the provisions of this section by an order of the secretary of state.

Proposed Register of Opticians

A deputation from the British Medical Association waited on the parliamentary medical committee at the House of Commons on the subject of the opticians bill. The object of the measure is to provide for the creation of a register of qualified opticians, and ultimately to prevent any nonregistered person from practicing as an optician. The bill is promoted by the four existing opticians' societies. Mr. N. Bishop-Harman, Mr. H. L. Eason, and other oculists attended to state the case for the British Medical Association against the bill. It was contended that the matter had assumed greater importance since the royal commission on health insurance had suggested that treatment of the eyes should be among the additional benefits to be granted. This would mean that ultimately there would have to be an oculist or optician in every town. The deputation urged that no cause had been shown for setting up another close corporation; that even if opticians charged smaller fees they could derive large recurring profits from supplying glasses, and that in the testing of the eyes a mistake due to lack of skilled knowledge might result in grave danger to the patient. It was mentioned that there are now 700 competent ophthalmic surgeons, that the number of men pursuing the special course is increasing, and that they will number 2,000 or 3,000 in a few years' time.

Strikers and Medical Students

The main cause of the early collapse of the general strike was the number and efficiency of the volunteers who carried on the essential services of the country. Among these, college students, including medical students, were prominent. The resentment aroused is shown by a letter from the secretary of the strike committee of the Transport and General Workers Union to the governors of Guy's Hospital, protesting against what he is pleased to call "blacklegging" by the students. The opprobrious term "blackleg" serves for argument and is applied indiscriminately to those who take the place of strikers, no matter how much the latter are in the wrong. The letter runs: "Our people have very long memories and will abstain from assisting the hospital when you are appealing for funds. My committee quite appreciate the fact that from the students' point of view it was only a 'rag' but would strongly point out it is a matter of bread and butter to us." Mr. H. L. Eason, superintendent of the hospital, replying on behalf of the governors, wrote: "During the strike the hospital remained open day and night, with its full service in every department, for the treatment of any person, striker or nonstriker, unionist or nonunionist, who might require assistance. No qualified medical officers, and no students whose services were required for the ordinary work of the hospital, were withdrawn from duty. You are probably not aware, that, in a large medical school attached to a hospital such as Guy's, there are a large number of students who are not required or employed for the actual work of the hospital. These students are free agents, and are not under the control of the hospital as regards their private or public actions. A number of them, no doubt, in common with the rest of the population, responded to the government's appeal to assist in carrying on those services which are essential to the community during a general strike, and for their work in this connection they have earned the gratitude of the public at large." The superintendent added that, even if the members of the union decided to withdraw their support, the hospital would continue, as in the past, to treat without any distinction all persons, whatever their political views, should they or their dependents require the services of the hospital. Of course it is both a false and a perfectly gratuitous assumption to say that the students undertook to help in the maintenance of the essential services of the country in any spirit of "rag"; they did it, like other good citizens, from a sense of duty, and thereby neglected for a time their studies. It is also rather strange that strikers who are engaged in cutting off the "bread and butter" of the whole population should complain about theirs being affected by the action of the students. Equally ridiculous is the threat to cut off subscriptions from a great hospital which provides free medical treatment mainly for the class to which they belong. But the widespread display of resentment against the various voluntary organizations that rescued the country from chaos and tyranny should prepare one for any absurdity. Forsooth, the unions have a perfect right to combine and elaborately prepare and launch an attack threatening the country with starvation, but the people so threatened have no right to combine to prevent this catastrophe. "This is a very wicked animal; when attacked, he defends himself," said a witty Frenchman, but our strikers do not seem to see the point.

Stephen Paget, F.R.C.S.

Mr. Stephen Paget, who practiced for some years as a surgeon but whose claim to distinction is mainly literary, has died at an advanced age. Born in 1855, the fourth son of Sir James Paget, he was educated at Christ Church, Oxford, where he took classical honors, and at St. Bartholomew's Hospital. He was appointed surgeon to the Metropolitan Hospital and later to the West London, and finally aural surgeon to the Middlesex Hospital. In 1910 he retired from practice and devoted himself entirely to literary work and to the defense of scientific investigation against the antivivisectionists and other cranks. In 1901 he first established his reputation as a writer by the publication of "Memoirs and Letters of Sir James Paget," a truthful and discriminating biography of his father, still much quoted. In the following year he edited his father's Selected Essays and Addresses. In 1919 he published a biography of Sir Victor Horsley, in which he dealt fairly with a difficult character, doing full justice to his great scientific achievements, but not allowing himself to be harnessed to the eccentricities of that polemical personality. In 1897 he contributed to a series of biographies, then being issued, a life of John Hunter, and in the same year an independent volume on Ambroise Paré and His Times. The most successful of his other books was "The Young People"; others were Confessio Medici (a book found helpful and much appreciated by members of the medical profession), "Essays for Boys and Girls," "I Sometimes Think," and "I Have Reason to Believe." He was master of a charming and natural literary style, which was inherited from his great father. In 1908 he founded with the help of other distinguished men (Professor Cushny, Sir Victor Horsley, Dr. Beevor, Dr. Head and Dr. Leonard Hill) the Research Defense Society, of which he was appointed honorary secretary. The energy which he devoted to this society was enormous: he became the protagonist in this country in the battle against the antivivisectionists. He wrote a host of pamphlets, lectured, debated, organized meetings and edited the journal, *The Fight Against Disease.* He spared no pains in confuting the calumnies and fallacies of the antivivisectionists, because of the hindrance they might be to the progress of science. His books dealing with this subject are most valuable. Even early in his career his interest was shown by his "Experiments on Animals," of which a third edition appeared in 1906. In 1912 he published "For and Against Experiments on Animals," and in 1914, "Pasteur and After Pasteur."

JAPAN

(From Our Regular Correspondent)

May 15, 1926.

Blind Men's Physical Development

Drs. Kiichiro Hasumi and Tadao Mori have published the results of their researches concerning the general physical consequences of loss of sight in students from 13 to 26 years of age. The blind students are generally below par physically. This poor state of physical development is mostly due to their lack of bodily exercise, but hereditary syphilis seems also to play an important part. Individual constitution, furthermore, may be the primary cause. A good number of those examined showed scoliosis. The loss of sight of the greater number is due to gonorrhea or syphilis, while in only a few does it seem to be due to nutritional trouble. A good many of them have Hutchinson's teeth, alveolar suppuration and caries. Many have respiratory disease.

Representative to the International Hygienic Conference

The ministries of home and education appointed Dr. Itsuma Takagi, medical expert of the government laboratory for the investigation of infectious diseases, as a Japanese representative to the international conference held in the Netherlands at the end of April.

Minimum Nourishment

Dr. Takahira and his assistant have discovered that minimum required nourishment varies: the harder the man's usual labor is, the more nourishment he requires; for instance, the metropolitan police naturally require more nourishment than the motormen and conductors of the street cars in Tokyo, who in turn require more than teachers of the primary schools in Tokyo. Casual laborers require more nourishment than people of any other class. In calculating the calories required by a man, the surface area of his body is the most important element. Accordingly, a gaunt, tall person requires more calories than a fat but short person. A simple method of measuring the surface area of a man's body, therefore, has become necessary.

The following exact formulas for measuring the surface area of a body have been published by Dr. Takahira and his assistants:

$$\text{Formula 1.}\quad A = W^{0.425} \times H^{0.725} \times 42.46$$
$$\text{Formula 2.}\quad A = W^{0.427} \times H^{0.718} \times 74.49$$

A = surface area of body in square centimeters.
W = body weight in kilograms.
H = height of body in centimeters.

Health Insurance

The health insurance laws, which were published in March, 1922, but which have not taken effect owing to the earthquake disaster of Tokyo, are to be put into force next July. According to the laws, the government or any health insurance association will issue to laborers compulsory or voluntary insurance against accidents, disease, death or childbirth. In case of accident or disease, physicians' fees and bills for medicines for 180 days will be paid by the insurers, and the insured will be allowed 60 per cent of their wages in order that they may pay living expenses while they are unable to work. They may call on any physician, dentist, specialist or pharmacist of those appointed by their insurers. In case of childbirth, the insured shall be paid the expenses of delivery and of a maternity hospital or a midwife, and shall be allowed in addition 60 per cent of their wages for twenty-eight days before the delivery and for forty-two days after it. In case of death, the policyholder shall be paid only the burial expenses, though an amount equal to the insured's wages for twenty days may be allowed.

Kato's Departure for the International Physiology Congress

Prof. Dr. Genichi Kato of the medical college of the Keio University, who is celebrated for his theory of decrementless conduction, left Tokyo for Europe, May 8, accompanied by four other professors in the same college, to make an experimental report on his new theory at the International Physiology Congress to be held in Stockholm next August.

Tuberculosis Patients in Korea

The government of Korea made an investigation of tuberculosis in Korea last year following the statistics that there were 11,939 cases, with 4,040 deaths. The greatest number of the patients were from 30 to 40 years old. Next in order were 695 young patients, aged 20 or so, and among them were 1,811 farmers, 810 merchants, and 523 patients without occupation. The incidence of tuberculosis was lower among fishermen than in any other industrial class.

Impotence of Workmen

Dr. Shogo Koinuma, medical expert of the home department, made an investigation of health conditions of 637 families of workmen in big storage battery factories in Osaka, Kyoto and Yokosuka, and in some big potteries. The statistics concerning 298 families of storage battery employees show the effect of lead intoxication on generative capacity:

Effects	Families	Percentage
170 workmen engaging in lead work:		
Sterility	42	24.7
Premature or stillbirth and miscarriage	26	8.2
Death of nurslings	70	24.2
128 workmen not engaging in lead work:		
Sterility	20	14.8
Premature or stillbirth and miscarriage	10	2.8
Death of nurslings	66	19.2

Infant Mortality

The statistics bureau of the Tokyo municipal office made an investigation in three wards of the city concerning the families of nurslings that died during the year May, 1924, to April, 1925. The Koishikawa ward is a healthful quarter of the capital that suffered least from the earthquake of 1923, while Honjo is an unhealthful quarter, on the river Sumida and Tokyo Bay, where the earthquake disaster was most severe and most of the laborers and workmen still live in barracks; nearly half of Shitaya suffered the disaster, but is now in course of reconstruction. The statistics show an inseparable relation between the death rate of nurslings and their parents' dwellings.

KOISHIKAWA Number of Rooms	KOISHIKAWA Number of Dead	HONJO Number of Rooms	HONJO Number of Dead
5 and more than 5	183	5 and more than 5	69
4	96	4	10
3	135	3	65
2	200	2	249
1	0	1	413

The main causes of their death are as follows:

Causes of Death	Number of Dead
Congenital abnormality, weak constitution and other diseases peculiar to nurslings	578
Pneumonia and bronchitis	474
Diarrhea and enteritis	432
Measles	82
Whooping cough	71
Bronchopneumonia	55
External troubles	39
Diseases of respiratory organs	29
Diseases of heart	25
Infectious or local diseases	20
Influenza	17
Other causes	337

BELGIUM

(From Our Regular Correspondent)

May 20, 1926.

Milk Legislation

The *Moniteur belge* contains an article giving an account of recent legislation pertaining to the production, transportation and sale of milk. To prevent adulteration or fraud, milk may be sold only in containers bearing labels indicating its quality: "whole milk," "skim milk," etc. Milk may not be offered for human consumption if produced by cows that are being treated with drugs that may affect the milk, if the flanks and udders of the animals are habitually covered with dung or if the cows have infectious diseases of the udders. Containers must not be of red or yellow copper, of wood, or of unglazed terra cotta ware. They must not be rusty or have a corrugated surface, nor may their walls be foul-smelling, or contaminated by milk settlings or other material. All containers must be kept in a perfect state of cleanliness by the use of hot water, steam or an alkaline solution applied daily. Milk bottles must be of uncolored, smooth glass, cylindric, with a flat bottom, wide opening and no projecting rim or shoulder. Before each refilling they must be cleansed and disinfected, by being dipped for at least ten minutes in a hot 5 per cent alkaline solution, cleaned with the aid of gravel, metal pellets or a brush, rinsed in clear water and allowed to drain. All deposits of organic matter must be removed. Siphons must be provided with a mechanical priming system. Paper containers must not be used more than once. Milk which comes from barns in which cows affected with contagious or infectious disease are kept may not be offered for human consumption. However, milk from barns in which are kept cows affected with tuberculosis (except tuberculosis of the udder) or foot-and-mouth disease may be offered for sale after having been pasteurized in the manner prescribed by the minister of health. Milk that has undergone changes through the action of micro-organisms or infectious products is prohibited (this includes acid milk that curdles on boiling; also viscous, putrid, bitter, blue or red milk). Milk may not contain preservatives, neutralizing substances, coloring matter or thickening substances. Excluded also is milk contaminated by impurities, such as particles of fodder or excrementa, hairs, flies, or settlings of organic matter, and which yields, after standing four hours or less, sediment equal to 0.5 cc. of impurities to a pink of milk, or which contains in a quart of milk more than 12 mg. of impurities insoluble in water, alcohol or ether, unless it can be shown by a fermentation test or by a bacteriologic analysis that microbes of putrefaction are absent.

CANNED MILK

Also the regulations governing the production and sale of canned milk have been published. Containers must bear labels indicating the nature of the product, such as "condensed whole milk," "sweetened condensed whole milk," "condensed skim milk" "or sweetened condensed skim milk." The label must also give the contents expressed in grams, and the name and address of the manufacturer or dealer. Milk in a state of fermentation, or containing antiseptics or coloring matter is prohibited.

Smallpox Vaccination

The Société de salubrité et d'hygiène publique of the province of Liége has called the attention of the people and of the public authorities to the efficacy of vaccination against smallpox and has pointed out the need of revaccination. It has expressed regret that vaccination certificates are not more rigorously demanded of children of school age.

Roentgenologic Examination of the Pericardium

Mr. Castex has presented to the Royal Academy of Medicine a communication on the use of lipiodol in the roentgenologic examination of the pericardium. He has employed it in cases of hemorrhagic tuberculous pericarditis, and it would seem that the method is destined to be widely used, owing to its value not only for diagnosis but also as treatment.

The Wassermann Test in Relation to Leprosy

Of twenty-four lepers examined by Dr. Van Den Branden, the Wassermann test was negative in fourteen, positive in five, and anticomplementary in one. The Wassermann test, which was positive in the four remaining cases, became negative in three after antisyphilitic treatment and remained only slightly positive in the fourth. These experiments show that the Wassermann test is generally negative in leprosy, the positive reactions appearing to be due to association with syphilis.

The Trypanosomiasis Expedition

Dr. Fourche has published a report on the trypanosomiasis expedition which was sent out by the Société forestière et minière du Congo, which spent from May, 1923, to May, 1925, in the company's territory. Dr. Fourche's report is an amplification of that of Dr. Schwetz, communicated in a previous letter. All the natives living in the concessions of the company have been examined and treated twice. The mission did not take charge of the workmen of the company until July, 1924, and they have received but the one treatment. At the first examination, about 30,000 natives were reviewed and examined. On the first revision, 40,000 persons, in addition to 20,000 workmen, were reviewed and examined, which included the natives of 750 villages and the workmen in camps. At the time of the first examination, 581 natives affected with trypanosomiasis received a complete course of treatment, and the author treated at least as many more suspects. Sterilization was accomplished in from 35 to 72 per cent, varying with the district, or 55 per cent, on the average. During the first revision, 960 natives affected (new and old cases, whether cured or not) were treated, and an equal number of suspects. During the last nine months, 400 affected workmen and an equal number of suspects were treated. The author holds the view that the number of persons affected ranges between 2 and 10 per cent in the various districts, the average for the whole territory on the left bank of of the Kasaï being 5 per cent.

The disease is still spreading but not rapidly—less rapidly in the East than in the West. Most of the physical difficulties that at first impeded progress have been overcome. The maps of the native territory and the surveys that have been made and are being kept up make it possible to control a population which, during the last two years, has become better disciplined and more confident. Dr. Fourche does not think that the sterilization of the whole population can be accomplished in a brief space of time, but the results secured thus far are very encouraging.

Experiments with Disinfectants

Some experiments on disinfectants carried out by the Institute for the Teaching of Public Hygiene in Cluj have reference to conditions of use in dwellings. Fluid disinfectants used were phenol (carbolic acid), calcium hypochlorite, mercuric chloride and sodium permanganate, while formaldehyde and sulphurous acid were the gaseous disinfectants tried. The organisms of typhoid, diphtheria, cholera and tuberculosis were selected, and were placed in solutions of broth, milk or melted gelatin as well as on cloth, unvarnished or unpainted wood, linen and wall paper. Formaldehyde vapor seemed superior to sulphurous acid in the case of tuberculous sputum, dried on linen or paper. Mercuric chloride, 1:1,000, destroyed all microbes; phenol, 5 per cent solution, all but anthrax spores. The length of exposure was twenty-four hours in each case. Calcium hypochlorite destroyed only the less resistant microbes, though it proved highly successful with anthrax spores on linen and paper. It was concluded that for highly resistant organisms, such as anthrax spores, mercuric chloride alone is absolutely certain; for tubercle bacilli, both mercuric chloride and phenol are efficacious; sodium permanganate and calcium hypochlorite are practically useless even in the case of slightly resistant organisms, in connection with which the other disinfectants, e. g., formaldehyde, sulphurous acid, mercuric chloride and phenol are fairly satisfactory. Evidence is accumulating to show that disinfection by spraying is the most trustworthy, and is most economical of time and expense.

The Prophylaxis of Malaria

Expeditions sent from Belgrade and Bucharest to some parts of Montenegro and Albania have dealt with the prevention of malaria. The commission recommends, as prophylactic agents, well built houses, freely ventilated and drained, and guarded by mosquito netting. Persons going out at night should have their heads, arms and feet properly protected from mosquitoes. The most efficient prophylaxis is large doses of quinine. The commission found the best results with 0.3 to 0.5 Gm. of quinine every four or five days. It considers permanent protection impossible by this means, and evolved a plan of prophylaxis based on the immunity acquired by some natives, owing to their having acquired the infection in childhood. The commission argues that quinine prevents the body becoming immune, because the malarial organisms are killed before the body has acquired the resistance necessary to complete immunity. It therefore gives sufficient quinine to prevent serious manifestations of the disease, but not sufficient to kill all the organisms in the blood. Thus, after a considerable time they bring about a permanent immunity.

The Climatic Treatment of Pulmonary Tuberculosis

Dr. Negulescu, chief physician of a leading climatic resort, does not believe that a high altitude is beneficial in pulmonary tuberculosis, because it expands the lungs. He states that shallow breathing is beneficial for a tuberculous patient, and that no breathing would be better still, on the ground that it is a good rule to put a sick organ at rest. Other Roumanian climatologists say that in acute tuberculous disease Dr. Negulescu's assertion may hold good, but that they cannot agree with him in regard to chronic cases.

Compulsory Notification of Pulmonary Tuberculosis

Dr. Catuneanu reported before the Bucharest Medical Society that voluntary notification of pulmonary tuberculosis has been unsatisfactory. In prevention work, early notification is necessary. The time appears ripe for compulsory notification of pulmonary tuberculosis, and the Bucharest city health board has recently decided to make the experiment. To date compulsory notification in certain central European cities has proved successful.

Unqualified Person as Director of a Veterinary Sanatorium

Recently a company was registered in Bucharest as the "Veterinary Sanatorium Limited" and was under the direction of a nonregistered veterinary surgeon, who described himself as "M.D., U. S. A., Specialist, Managing Director." An injunction was applied for by the Association of Roumanian Veterinary Surgeons through the public prosecutor, and was granted. It was held that, although the limited company was not a person, within the meaning of the competent act, the title used, viz., "M.D., U. S. A., Specialist, Managing Director of the Veterinary Sanatorium Limited," led to the inference that the director was a practitioner of veterinary surgery, contrary to the provisions of the act, and that, consequently, an injunction must be granted, restraining both the company and the managing director from using any description of such director indicating that he was a veterinary surgeon or a practitioner of veterinary surgery or any branch thereof.

The German Surgical Society

The celebration of the fiftieth anniversary of the founding of the Deutsche Gesellschaft für Chirurgie, under the chairmanship of Körte, was a pronounced success. In honor of the occasion, the *Deutsche medizinische Wochenschrift* issued a memorial edition containing twenty-eight articles by eminent surgeons of various countries, six of the articles being written by Americans. The *Zentralblatt für Chirurgie* also issued a special number.

Bircher of Aarau, Switzerland, presented in the name of the Schweizer Gesellschaft für Chirurgie a bronze statue of von Haller. Bauer of Stockholm read a treatise in Latin issued by the Swedish surgical society.

Von Eiselsberg of Vienna delivered the opening address on "Problems of Surgery of the Brain and Spinal Cord." The researches of Fritsch, Hitzig and others laid the foundation for this branch of surgery. In Bergmann's time surgeons scarcely ventured to operate on the anterior central gyrus. Today surgeons no longer hesitate to operate on any part of the brain, with the exception of the pons and the medulla oblongata. The main thing is a prompt and correct diagnosis, for which an intimate collaboration of neurologist and surgeon is essential. Encephalography has not contributed what was expected of it. It has, however, considerable value for the differentiation of hydrocephalus and brain tumors. Von Eiselsberg does not employ it for localization purposes, but prefers, if necessary, an exploratory exposure of the brain. Tumors of the region of the auditory nerve, which, as recent researches show, are for the most part benign neurinomas, do not need to be radically eliminated. This finding makes for a better prognosis, since they can be favorably influenced by postoperative roentgenization. In fact, in general, roentgenray treatment of brain tumors has a good effect. The injection of lipiodol by way of the suboccipital cisterna is of great importance for the recognition of tumors of the spinal cord. In eighty-nine tumors, eighty-four operative cures were effected. Also the remote results were good. Inoperable tumors should be treated with roentgen rays, whereby good effects, and in some instances cures extending over a period of two and a half years, may be secured. Early diagnosis together with observation of every case of obstinate headache, and early operation when indicated, are the principal aims to be achieved.

Fedor Krause of Berlin spoke on the operative treatment of epilepsy. The treatment of jacksonian epilepsy is based on the recognition of the focus which gives rise to the attack and on its operative removal. This requires a most exact observation of attacks. It often appears as if the convulsion began in one of the extremities, but it is preceded by an ocular manifestation or a turning of the head, which may last only a few seconds and therefore easily escapes observation. In such cases, one would be wrong in attacking the motor center of the extremity concerned. In other cases, the attack is preceded by an aura of visual, auditory or olfactory hallucinations. In contradistinction to jacksonian epilepsy, he does not regard true epilepsy as ordinarily amenable to surgical treatment. Only when the attacks begin with typical local symptoms is surgical intervention indicated. Even in jacksonian epilepsy, intervention must be early.

Guleke of Jena dealt with the clinical aspects of neurinomas, of which he distinguished three groups. To the first group belong neurinomas found in various parts of the brain and which are exemplified by tumors of the auditory nerve. Second, tumors found along the vertebral canal usually originate in the posterior roots and may develop along the transverse processes. The third group occurs along the peripheral nerves (sciatic, peroneal). Two thirds of the neurinomas were found at the points of exit of the nerves. The neurinoma is hard to distinguish from the neurofibroma and the sarcoma.

The second address was given by E. Rehn of Düsseldorf on "Surgery and Organic Function." Organic function is life itself; disease is a complex of functional disturbances. The speaker mentioned a new type of patient that is endangered by operation; namely, the so-called embolic, who is represented as pale of skin, corpulent, and unable to cope with severe mental and physical exertion. A comparison of the blood coagulation curves shows a markedly increased coagulability. Further dangers lie in endocrine disturbances. Soma and psyche cannot be separated. The surgeon must be able to influence also the psyche. The vagotonic patient is a poor surgical risk. He is more likely to suffer from shock, and local anesthesia should be avoided in his case because of the danger from drop in blood pressure. The disturbances can be prevented by the use of calcium chloride urea. Anesthesia may cause severe disturbances in the liver and bile ducts, especially in patients with chronic liver affections. The speaker emphasized that infusions of sodium chloride and dextrose are not always indicated. Blood transfusions are better. In preoperative examination of the heart the Kaufmann functional test is appropriate, or the patient may be required to inflate ten times a pneumatic ring. Prophylactic administration of digitalis is recommended in selected cases. Calcium chloride urea may be injected as a prophylactic in pulmonary affections. Both kidney and liver function should be tested. Thus, the surgeon must occupy himself more and more with physiology. Every organ is a part of the whole organism. Wounds heal better on an acid than on an alkaline diet, although care must be taken to preserve a certain alkali reserve in the body.

Haberer of Graz spoke on the sparing of tissue in operations. Loss of blood and bruising of the tissues must be avoided. If the tissues are spared, scar tumors, adhesions and thrombi are less frequent and the danger of embolism is lessened. He thinks that some of the postoperative lung complications are due to small emboli.

Kirschner of Königsberg discussed the treatment of suppurative generalized peritonitis. His statements were based partly on cases occurring in the Königsberg clinic and partly on 10,000 further cases in twenty-three clinics and hospitals. The statistics reveal a high mortality in early childhood up to age 5, a decrease up to age 15, and then a gradual increase from the fifth decade on. The mortality increases from 24.9 per cent in the first twelve hours to 32.4 per cent in the second twelve hours, 45.5 per cent when the operation is performed the second day, and 66.6 per cent when the operation is delayed beyond forty-eight hours. For eliminating the exudate found in the abdominal cavity, Kirschner recommends irrigation with physiologic sodium chloride solution if the exudate is rather evenly distributed over the abdominal space and collections of filth are visible; if the material to be removed is distributed over a small area, "dry mopping" is indicated. He is opposed to the introduction of medicaments into the abdominal cavity. If every focus of infection can be effectively eliminated, the wound should be closed without drainage. If that is not possible, then only the circumscribed focus of infection should be drained. Gauze may be used to wall off the focus of infection from the remaining abdominal cavity. Drainage of Douglas' pouch, and the Rehn-Fowler position, Kirschner regards as useless. It is of greater importance that the patient assume a comfortable horizontal position. Camphor preparations have not proved as valuable as digitalis, epinephrine and, above all, morphine. The ingestion of fluids should be so regulated by the rectal and intravenous drip methods that the amount of urine voided daily be from 1 to 1.5 liters. Some intestinal activity is needed to remove toxins that may have collected in the intestine. Furthermore, it serves, as Usadel of Königsberg has shown by experiments, to stimulate blood flow in the portal circulation, in which in peritonitis and intestinal paralysis stagnation often occurs. When intestinal paralysis has persisted, Kirschner has seen improvement result in very severe cases from enterostomy and multiple percutaneous punctures of the intestine. As a result of the following out of these principles, the mortality of the Königsberger clinic has been reduced from 87.5 per cent to 30.1 over a period of thirty years. Early operation and improvements in technic have contributed to this satisfactory result.

Mention of the numerous individual papers must be omitted for lack of space.

Marriages

John Calvin Cox, Maplewood, N. J., to Miss Florence Becker of Hilton, April 23.

Edward Vincent Milholland to Miss Rose Marie Barry, both of Baltimore, June 2.

Walter D. Hammond, Minneapolis, to Miss Esther Mae Huff of Seattle, May 19.

Deaths

Franklin Emmett Wallace ⊕ Pueblo, Colo.; Rush Medical College, Chicago, 1896; member of the American Academy of Ophthalmology and Oto-Laryngology, the Colorado Ophthalmological Society and the Colorado Oto-Laryngological Society; Spanish-American War veteran; formerly city physician of Monmouth, Ill., and coroner of Warren County, Ill.; aged 58; died, May 23.

Edward Parks Hall ⊕ Kansas City, Mo.; Ensworth Medical College, St. Joseph, 1897; member of the American Academy of Ophthalmology; professor of otorhinolaryngology, University of Kansas School of Medicine, Rosedale; served during the World War; aged 49; died in May, of chronic myocarditis and mitral insufficiency.

William R. Brooksher ⊕ Fort Smith, Ark.; Kentucky School of Medicine, Louisville, 1891; member of the Radiological Society of North America; past president and secretary of the Sebastian County Medical Society; aged 61; died, May 19, of septicemia.

Sumner Danforth Davis, Jermyn, Pa.; Medical School of Harvard University, Boston, 1869; also a druggist; for fifteen years postmaster; formerly secretary of the board of health and for thirty-two years health officer; aged 80; died, April 11.

Morris Printz ⊕ Denver; University of Colorado School of Medicine, Denver, 1918; aged 31; died in April, of septic sore throat and acute lymphatic leukemia, while attending the annual session of the American Medical Association.

Haughton Baxley, Markham, Va.; College of Physicians and Surgeons, Baltimore, 1889; one of the founders of the Maryland Medical College and the Franklin Square Hospital, Baltimore; aged 58; died, May 28, of pneumonia.

David Jasper Hill, Lexington, N. C.; College of Physicians and Surgeons, Baltimore, 1893; member of the Medical Society of the State of North Carolina; aged 62; died, May 13, at Winston-Salem, of angina pectoris.

Elliott Swift Riggs, Washington, Pa.; Jefferson Medical College of Philadelphia, 1869; member of the Medical Society of the State of Pennsylvania; Civil War veteran; aged 83; died, May 2, of cerebral hemorrhage.

John Columbus Hammack, Walkertown, N. C.; College of Physicians and Surgeons, Baltimore, 1895; member of the Medical Society of the State of North Carolina; aged 58; died, May 15, of myocarditis.

Charles Paul Pike, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1885; member of the Medical Society of the State of Pennsylvania; aged 72; died, May 1, of myocarditis.

William Divine Davis ⊕ St. Louis; Washington University Medical School, St. Louis, 1909; member of the St. Louis Dermatological Society; aged 38; died suddenly, May 20, of chronic myocarditis.

Richard Gilbert Ayer, Honolulu, Hawaii; Medical School of Harvard University, Boston, 1891; member of the Hawaii Territorial Medical Association; aged 58; died, March 30, of lobar pneumonia.

Charles Cross ⊕ San Francisco; Cooper Medical College, San Francisco, 1895; served during the Spanish-American and World wars; aged 62; died, March 24, of cerebral hemorrhage.

John William Elliott ⊕ Sharon, Pa.; Western Reserve University School of Medicine, Cleveland, 1889; Jefferson Medical College of Philadelphia, 1890; aged 67; died, April 19, of pneumonia.

Frank P. Peyton, Mexia, Texas; Louisville (Ky.) Medical College, 1888; member of the State Medical Association of Texas; aged 71; died, May 14, at the Brown Hospital, of pneumonia.

Edith Sara Brownsill ⊕ Berkeley, Calif.; University of California Medical School, San Francisco, 1904; on the staff of the Bates Sanitarium; aged 54; died, April 26, of heart disease.

Louis J. Herget, Louisville, Ky.; Louisville Medical College, 1894; member of the Kentucky State Medical Association; aged 54; died, May 8, of a self-inflicted bullet wound.

Gerhard Arthur Isselstein, Dayton, Ohio; Ohio State University College of Medicine, Columbus, 1925; aged 26; died, May 4, at sanatorium in Colorado Springs, of tuberculosis.

Powhatan Moncure, Bealeton, Va.; Medical College of Virginia, Richmond, 1884; member of the Medical Society of Virginia; aged 65; died, May 3, of arteriosclerosis.

James Cullen Keaney, De Soto, Mo.; Homeopathic Medical College of Missouri, St. Louis, 1874; aged 88; died, May 4, at St. Mary's Hospital, St. Louis, of lobar pneumonia.

James Crowe ⊕ Huntingdon Valley, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1904; aged 48; died, May 1, of pneumonia, following influenza.

Isaac Newton Presley, Ellettsville, Ind.; Beach Medical Institute, Indianapolis, 1885; Civil War veteran; aged 81; died, February 28, at Bridgeport, of paralysis.

Achilles Walter Cook, Wheatland, Iowa; Keokuk Medical College, 1891; aged 60; died, May 26, at the Jane Lamb Hospital, Clinton, of carcinoma of the throat.

William G. W. Tupper, Minneapolis; University of Michigan Medical School, Ann Arbor, 1884; aged 65; died, May 8, at the Eitel Hospital, of coronary sclerosis.

William J. McWaters, Bragg City, Mo.; University of Tennessee College of Medicine, Memphis, 1901; aged 56; died, May 9, of carbolic acid poisoning.

John William Miller, Chinnville, Ky.; Eclectic Medical Institute, Cincinnati, 1905; aged 70; died in May, of carcinoma of the face, and arteriosclerosis.

Frederick Wilhelm Froehling ⊕ Kansas City, Mo.; University of Leipzig, Germany, 1891; aged 62; died in May, of carcinoma of the gallbladder and liver.

Alexander C. Schuman, Louisville, Ky.; University of Louisville School of Medicine, 1875; aged 85; died, May 9, of arteriosclerosis and asthma.

George C. Kingsbury ⊕ Largo, Fla.; Miami Medical College, Cincinnati, 1880; aged 67; died, May 19, of acute mastoiditis and diabetes mellitus.

Alonzo P. Baker, Herrin, Ill.; Medical College of Ohio, Cincinnati, 1875; Civil War veteran; aged 77; died, May 21, of heart disease and asthma.

Marion L. Rice Berneike, Anaheim, Calif.; University of Michigan Medical School, Ann Arbor, 1874; aged 75; died, February 3, of myocarditis.

Willis Pearl Middleton, Acton, Mass.; Tufts College Medical School, Boston, 1912; aged 36; died, April 2, of pneumonia, following influenza.

Ulric J. Lalonde, Montreal, Que., Canada; Laval University Faculty of Medicine, Quebec, 1891; aged 63; died recently, following a long illness.

Harmon Jasper Rossiter, Deertrail, Colo.; Eclectic Medical University, Kansas City, 1918; aged 44; died, May 7, of carcinoma of the stomach.

Buford Thomas Wood, Danville, Ky.; University of Louisville School of Medicine, 1873; aged 76; died, May 14, of cerebral hemorrhage.

George B. Buckingham, Brookville, Ind.; Kentucky School of Medicine, Louisville, 1879; aged 74; died suddenly, May 15, of heart disease.

Ralph B. Crawford, Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1882; aged 85; died, April 11, of myocarditis.

Stephen Goodhue Bailey, Lowell, Mass.; Boston University School of Medicine, 1880; aged 81; died, March 31, of carcinoma.

Nathan Edward McAlister, Portland, Ore.; University Medical College of Kansas City, Mo., 1897; aged 57; died, March 31.

Laban Hazeltine, Jamestown, N. Y.; College of Physicians and Surgeons, Baltimore, 1880; aged 73; died, May 10, of uremia.

Harrison D. Cooper, Dexter, Kan. (licensed, Kansas, 1901); aged 68; died, March 15, of cerebral hemorrhage.

Franklin Pierce Amdor, Sand Springs, Mont. (licensed, Iowa, 1887); aged 76; died, March 28.

Carl Wintrich, Chicago (licensed, Ohio, 1896); aged 79; died, April 30, of chronic myocarditis.

L. D. Coffman, Poetry, Texas (licensed, Texas, under the Act of 1907); aged 59; died, March 21.

Thomas F. Clark, Belpre, Kan. (licensed, Kansas, 1901); aged 83; died, March 4, of paralysis.

E. P. Davenport, Craigville, Ind. (licensed, Indiana, 1897); died recently, of paralysis.

J. W. Miller, Morrisville, Mo. (licensed, Missouri, 1883); aged 85; died, April 21.

The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

L. M. HUNTER'S EPILEPSY CURE

Mail-Order Quackery in Little Rock, Arkansas

LaFayette M. Hunter, M.D., Little Rock, Arkansas, conducts a crude piece of mail-order quackery under the trade name "The Dr. Hunter Laboratories," selling a mail-order "cure" for epilepsy. Some months ago the stationery of "The Dr. Hunter Laboratories" declared that its "secretary" was one H. S. Brevoort, M.D. What are the professional histories of these professional gentlemen?

HUNTER'S RECORD

According to our records, LaFayette M. Hunter was born in Kansas in 1888, and received a diploma from the Eclectic Medical University of Kansas City, Missouri, in 1913. This institution, which went out of existence in 1918, was a low-grade affair that was not recognized even by the state in which it operated: in fact, forty of the forty-eight states in the union refused to recognize its diplomas. At the time that Hunter obtained his diploma the Eclectic Medical University had for its secretary D. R. Alexander, whose later institution, the notorious Kansas City College of Medicine and Surgery, was so deeply involved in the nation-wide medical diploma-mill scandal of 1924-1925. The same year that Hunter received his diploma (1913) he also obtained a license in Arkansas through the Eclectic Board—probably the easiest way to obtain a license to practice medicine in the United States

In 1916 L. M. Hunter and H. S. Brevoort were operating a quack advertising office at Pittsburg, Kansas. According to the Police Department of Pittsburg, Kansas, Hunter while there was arrested at least twice for running a house of prostitution and on both occasions he forfeited his bonds and was found guilty and fined. Hunter left Pittsburg early in 1917 and word was next received that he was in Dodge City, Kansas, connected with the "United Doctors" quackery. In 1919 Hunter was at Coffeyville, Kansas, where he conducted "The Dr. Hunter's Institute of Healing," part of whose advertising material was a four-page sheet, *Health Talk*, edited by H. S. Brevoort. In 1921 Hunter was conducting an advertising office that he called "The Hunter Clinic," from Little Rock.

It is worth noting at this point that, although Hunter apparently practiced medicine for many years in Kansas, he never, so far as our records show, was legally licensed to practice medicine in that state. He had no difficulty, apparently, in getting an Eclectic license to practice in Arkansas—a state that is notorious for the ease in which owners of diplomas from diploma mills can obtain licenses through its Eclectic Board. The mail-order epilepsy cure now being conducted under the trade name The Dr. Hunter Laboratories seems to be an outgrowth of Hunter's so-called clinic.

BREVOORT'S RECORD

The professional record of H. S. Brevoort is about as unsavory as that of Hunter. Brevoort, according to our records, received a diploma in 1893 from the Medical Department of Omaha University. In 1896 he was reported to be at Arapahoe, Nebraska; about a year later in Scott, Kansas, and then at DuBois, Nebraska. He is said to have had to leave DuBois "between days" under circumstances that at this time it is not necessary to detail.

Some time later he practiced medicine and operated a drug store in Reeds Spring, Missouri, going from there to St. Joseph, Missouri, where, in 1913, he was in charge of the "United Doctors" quackery at that place. For three or four years he was at Hutchinson, Kansas, later going to Coffeyville, Kansas, where, as has already been stated, he was connected with Hunter. In 1923 he had gravitated to Arkansas.

Although Brevoort's name appeared for some time on the stationery of the Hunter Laboratories, the man, so far as our records show, has never been licensed to practice medicine in Arkansas. He has not even a license from the Eclectic Board of that state. Brevoort's name no longer appears as "secretary" of the Hunter mail-order quackery. His name is now used by Hunter in connection with the "come-on" literature. Hunter reproduces a letter in which Brevoort states that, as a physician, he takes pleasure in recommending Hunter's treatment. Brevoort now, it seems, is at Wichita Falls, Texas. His stationery notifies the public that he has a "Practice Limited to Office Treatment of Chronic and Rectal Diseases."

ENTER L. L. MARSHALL

One other point is worth noting before discussing Hunter's nostrum and its method of exploitation. An Eastern newspaper that recently was offered some advertising of the Hunter quackery rejected the advertisement. Shortly thereafter the paper received a letter from the advertising agency that submitted the advertisement, reading in part as follows:

> "You have returned to us ad. of Hunter Laboratories, with notation 'Adv. not acceptable.'
>
> "However, in view of the fact that we have received a letter from Dr. L. L. Marshall of the State Board of Health of Arkansas—which we quote below—we are re-submitting the copy to you.
>
> "This is to certify that I have examined the product of the 'Dr. Hunter Laboratories' of this city, namely: 'Dr. Hunter's Rational Treatment for Epilepsy.' The Product conforms with the Pure Food & Drug Act and contains no opiates or habit forming drugs. I have also noted their advertising and it is not exaggerated. (Signed) L. L. MARSHALL, M D, Member State Board of Health."

This use of the name of the State Board of Health of Arkansas to bolster up a medical mail-order fake should be of interest to the citizens of that commonwealth. L. L. Marshall, we regret to say, is a member of the State Board of Health of Arkansas, having been appointed Jan. 1, 1925. The Marshall testimonial, as quoted by the advertising agency, in itself, indicates the professional status of the man, but that is not all. Our records show that Louis Linn Marshall was born in 1881, and got a diploma from the same wretched school that gave one to Hunter—the Eclectic Medical University of Kansas City. Marshall secured his diploma in 1912, and was immediately licensed in Arkansas—of course, by the Eclectic Board. In applying for his license in Arkansas, Marshall declared that he had attended four full courses of medical lectures, the first three years of which were alleged to have been at the Denver Homeopathic Medical College, Denver, Colorado, from September, 1903, to April, 1906. THE JOURNAL has evidence that shows that Marshall did not attend the Denver Homeopathic Medical College. The official list of matriculants of the Denver Homeopathic Medical College for some years before Marshall claims attendance until the school became extinct in 1909 fails to show Marshall's name. The person who endorsed Marshall's application for examination before the Arkansas Board, and declared him to be "a person of high moral character and worthy of professional recognition," was D. R. Alexander of Kansas City, who then was secretary of the institution that granted Marshall a diploma, and the man whose notorious Kansas City diploma-mill, during the past year or two, has made a record that smells to heaven.

When Marshall was in Kansas City and before he had even so poor a medical prop as a diploma from the Eclectic Medical University, he was connected with a concern known as the Samaritan Hospital. Kansas City papers in the spring of 1912 reported that L. L. Marshall, president and manager of the Samaritan Hospital, and one James M. Martin, alias "Dr. F. W. Lanoix," were in the county jail charged with causing the death of a woman by criminal operation. At that time D. R. Alexander was secretary of the Samaritan Hospital. Kansas city papers at that time printed a picture of Marshall bearing the legend "L. L. Marshall, one of the Samaritan Hospital Charlatans." Marshall's case never came to trial. The matter dragged along for some months and the papers reported that, after the state had spent much money in gathering evidence, the cases against Marshall (charging him with manslaughter in the second degree and practicing medicine without a license) were dismissed. Marshall's activities before he went into the medical field need not, at this time, be discussed.

THE "CURE" ITSELF

So much for the professional elements in the personnel of Hunter's mail-order epilepsy cure. The cure itself and its methods of exploitation differ not a great deal in their sordid details from those of average medical mail-order quackery Hunter emphasizes in his advertisements the falsehood that his treatment "stops seizures from the first day used." Those who answer the advertisement first receive letter no. 1 of the follow-up series. With the first letter there is the usual batch of printed testimonials—without names or addresses! There is also a six-page leaflet in which Hunter states that he has been an interested and close student of epilepsy ever since he was "in charge of the insane and epileptic department of a large charity institution." He adds that there was, until recently, no reliable remedy for epilepsy, but "now in the latter end of my long professional career" (this line of hokum was sent out by Hunter less than ten years from the time he got his diploma from the Eclectic Medical University of Kansas City) "a true specific for epilepsy has been found." If the first letter fails to bring an order, the second letter of the follow-up series comes ten days later. Letters 3, 4, 5 and 6 come at regular ten-day intervals, each being a little more insistent than its predecessor. Then comes the seventh letter, which attempts to combine all the persuasiveness of the previous six in an effort to extract the $5 necessary for one "treatment." If this fails of its object, Hunter apparently drops that name from his list for about a year, when he makes a final effort.

H. R. BREVOORT, M. D.
Physician in Charge
DR LAFAYETTE M HUNTER

Some of the older advertising of Hunter and Brevoort together with Hunter's present piece of quackery—the epilepsy cure.

In a form-letter sent out in July, 1924, Hunter says: "Fifteen years ago, when I graduated from medical college and stood on the threshold of my medical career. . . ." The facts are, as has already been stated, Hunter got his diploma in 1913, eleven years before this letter was sent out, which would indicate that he finds it difficult to stick to the truth even in chronological matters.

Five dollars was sent to the "Dr. Hunter Laboratories" for a complete "course" of "Dr. Hunter's Rational Treatment for Epilepsy." In due time the small package that was received, containing the treatment, was turned over to the A. M. A. Chemical Laboratory for analysis. The laboratory reported as follows:

LABORATORY REPORT

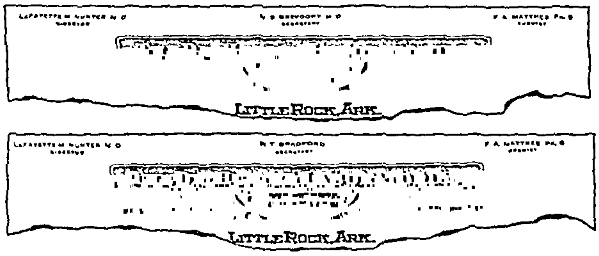
"One original package of Dr. Hunter's Rational Treatment for Epilepsy (Dr. Hunter Laboratories, Little Rock, Ark.) was submitted to the A. M. A. Chemical Laboratory for examination. The package contained fifty pink colored capsules containing a white, odorless, almost tasteless, faintly gritty powder; the average weight of the contents of each capsule was 0.27 Gm. (approximately 4.2 grains). No statement as to the composition was given on the trade package or in the accompanying circular. Qualitative tests indicated the presence of milk sugar and phenobarbital ("luminal"). Alkaloids, heavy metals, bromides, iodides, organic acids, were not found.

"Quantitative determinations yielded the following:

"Loss on drying	2.6 per cent.
"Phenobarbital	24.8 per cent.
"Lactose (milk sugar)	72.7 per cent.

"From the foregoing it may be concluded that each capsule of 'Dr. Hunter's Rational Treatment for Epilepsy' contains essentially 0.07 Gm. (approximately 1 grain) of phenobarbital (luminal), to which has been added lactose (sugar of milk)."

From the report just given it will be seen that this alleged "true specific for epilepsy," which "stops seizures from the first day used," is simply phenobarbital (luminal). The directions which come with the treatment tell the victim to take six capsules a day until a drowsiness appears, and if drowsiness fails to appear by the third day, to take eight capsules a day. He is told further that if the dosage required to produce drowsiness fails to control the seizures, another capsule should be added to the dose.



LITTLE ROCK, ARK.
LITTLE ROCK, ARK.

The letter-heads of the "Dr. Hunter Laboratories," showing that H. S. Brevoort used to be directly connected with fakery. Today Brevoort's connection is a testimonial letter puffing the Hunter nostrum.

Phenobarbital (luminal) is a powerful drug of distinctly habit-forming tendencies. Its sale in the British Isles is controlled under the Dangerous Drugs Act and it can be sold only on a physician's prescription. In this country there is no state or national control in the sale of either phenobarbital (luminal) or of the less dangerous barbital (veronal); the presence of luminal does not even have to be declared on the label under the regulations of the Food and Drugs Act, and, although it is distinctly poisonous and therefore should be debarred from the mails, as provided in the postal laws and regulations, it is being sent broadcast to any one that orders it by various mail-order quacks, of which L. M. Hunter is but one.

Phenobarbital (luminal) is more toxic than barbital (veronal). Those who have had large experience with the drug declare that it should never be prescribed in single doses of more than 1½ grains, and not more than 3 grains should be taken in twenty-four hours, because of the very slight difference that exists between the therapeutic dose and the fatal dose. Hunter tells his victims at the outset to take from six to eight grains daily. As phenobarbital frequently produces severe skin rashes, gastro-intestinal symptoms and nephritis, it should be administered only under the direct control of a physician.

In spite of these facts, well known to the medical profession, quacks like Hunter sell indiscriminately, without let or hindrance, phenobarbital in secret mixtures under proprietary names and without any hint of the fact that the stuff is phenobarbital. In addition, they charge an exorbitant price for the product. Hunter, for instance, charges $5 for 50 grains of phenobarbital in capsule form—ten cents a grain. The retail price of phenobarbital is less than one and one-half cents a grain. The financial feature, however, is of but minor importance; the serious fact is that quacks are permitted to send a dangerous drug, hidden under a proprietary name, to victims of epilepsy under the claim that it will cure this condition. That is what L. M. Hunter is doing today with the indirect aid and assistance of H. S. Brevoort, and a member of the State Board of Health of Arkansas, L. L. Marshall.

Correspondence

"SELECTING A HOSPITAL FOR INTERNSHIP"

To the Editor:—Unfortunately, some institutions have felt that, not being included in the table which accompanies my paper entitled "Selecting a Hospital for an Internship" in The Journal, May 15, indicates that they may not be acceptable for internship. The table covers only a few cities and serves merely as an example of how the percentage of necropsies may be a guide to the quality of the work of a hospital.

There are numerous hospitals in the country, not included in the table, that have a 25 per cent or greater percentage of necropsies. All such should be regarded as acceptable for an internship. Prospective interns should make inquiry of any hospital under consideration as to its number of deaths and number of necropsies per annum, among other information sought; any hospital should be willing to give this information.

Henry A. Christian, M.D., Boston.

DUODENAL TIPS

To the Editor:—In The Journal, May 22, are descriptions of two new duodenal tips. Thus, by the inventions of Carl V. Vischer and Moses Einhorn the armamentarium of the gastro-enterologist is enriched (or emburdened) by two new modifications of the instrument which seems to baffle so many minds.

Each one of these tips, as well as each of those previously devised by others, is the easiest for the physician to introduce, the least disagreeable for the patient to swallow, passes into the duodenum in the shortest possible time, and affords the best drainage by virtue of this, that or the other qualities it possesses. It is amusing to see on the very same page the same advantages claimed for one tip because of its being the largest and heaviest as yet devised, and for the other being the smallest and lightest.

Is it really the design of the duodenal tip used that determines its easy and quick passage into the duodenum? Judging from the number of duodenal tips already on the market and new ones produced every now and then, one would conclude that this is the case. In my opinion, the size, shape, weight, etc., of the tip play a very unimportant part in accomplishing a successful duodenal intubation. One who carefully follows the generally accepted rules as outlined in Dr. Moses Einhorn's communication cannot help noticing that it is not the tip that counts but a combination of many other factors, not the least being the skill with which the procedure is performed. The condition of the nervous system of the patient on any particular day, the condition of the pylorus, the amount of gagging produced in introducing the tube, the rate at which the patient swallows the tube—all these count for much more than the type of tip employed. It is common experience to have the same tube and tip pass into the duodenum with the same patient in fifteen or twenty minutes on one day and take several times that long on another. The only advantage of a large tip over a small one is that it is easier to locate it under the fluoroscope, especially when intubating a stout patient. With the average patient, it matters very little what kind of a tip one uses. The less one relies on the wonderful qualities of any particular tip, the more attention he will pay to the other details of the procedure and the better the results.

DISTRIBUTION OF PHARMACEUTIC SAMPLES

To the Editor:—I desire to call your attention to the growing and pernicious custom of drug houses in mailing their literature and samples to the homes of physicians. I regret to note that some of the better pharmaceutic firms are also entering into this practice. The average daily mail contains from one to a dozen circulars, many of which are not desirable for a home library table, and certainly not elevating reading for children. Many of the samples are laxatives and douche powders containing poisons and are a menace to the home.

I simply call this matter to your attention, hoping for general disapproval and thereby securing cooperation sufficient to stop this bad method of advertising.

Charles M. Nice, M.D., Birmingham, Ala.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SARCINAE IN GASTRIC CONTENT AND IN URINE

To the Editor:—What is the pathologic significance of *Sarcina* in the stomach and urine? Is there any relationship? Could you give me references to authorities or publications where this information may be treated?

Robert F. Wilcox, M.D., LaPorte, Ind.

Answer.—*Sarcina ventriculi* is found frequently in the gastric contents in cases of long continued obstruction due to ulcer with high acidity. In these cases there is extensive fermentation, with the formation of large numbers of these organisms. They are also found in the feces in cases of obstruction due to ulcer. *Sarcina* is exceptionally found in the urine. It is smaller than the gastric sarcina, from which it is developed by transmission through the urethra. The urine being an unfavorable medium for its cultivation, the sarcina produced in it is imperfectly formed. The organisms are usually, if not always, accidentally introduced into the bladder by catheterization.

TREATMENT OF BRONCHIAL ASTHMA

To the Editor:—I have a patient suffering from bronchial asthma, with excessive coughing. Epinephrine relieves her temporarily. What is the best known treatment? Can you suggest good literature on the subject?

M.D., West Virginia.

Answer.—Asthma is not a disease but a syndrome of at least two different etiologic types: (1) protein hypersensitiveness (allergy) and (2) bacterial infection. In both, a predisposing element in the nervous system must be recognized. This is partly psychic, so that an attack may come on merely because the patient expects it. Fatigue undoubtedly plays a part, so that the loss of sleep produced by attacks favors their continuation, thus establishing a vicious circle. There is also an excessive irritability of that part of the vagal nervous mechanism which controls the motor and secretory activity of the bronchi; and, the more frequently this mechanism is set into action, the more irritable it becomes. The part played by the nervous system emphasizes the importance of prompt and efficient treatment of the attack, nothing better for which has yet been advanced than the intramuscular injection of epinephrine solution, which sometimes acts satisfactorily in doses of 0.1 cc., though as much as 1 cc. may be required. It acts best and in smallest doses when used at the first warning of an attack. Hence the patient must be entrusted with its injection. Sedatives such as phenobarbital and amidopyrine, and antispasmodics like atropine or scopolamine lessen the liability to attacks, and the need for epinephrine injections.

In the allergic type of asthma, the protein to which the patient is hypersensitive must be discovered and he must be protected from it or immunized against it. In the infectious type, specific immunization by means of autogenous vaccine is likely to be of value. Anything that improves the bronchitis present in the infectious form lessens the tendency to asthmatic attacks. This is the way iodide or arsenic acts.

Modern views on the nature and treatment of asthma are presented by:

COCKROACHES

To the Editor:—What makes water bugs and croton bugs so common in our homes and what can be done to get rid of them?

M.D., Pennsylvania.

Answer.—The wide distribution of cockroaches is brought about chiefly through maritime trading. Of the various species, the croton bug, *Blatella hermanica* Linn., and the oriental roach, *Blatta orientalis* Linn. are most widely distributed. The cockroach can be controlled in dwellings, restaurants and similar situations. One of the most important procedures for ridding premises of these pests is the careful cutting off of their food supply, such as scraps of food or ill fitting food containers. The larger forms can be trapped in a deep, smooth-walled vessel (fruit jar or the like) in which is placed a favorite roach food, such as chocolate or molasses. Sticks leading to the top of the jar enable the roaches to reach the mouth of the jar, whence they tumble into the trap in trying to reach the food. If the trap contains liquid the roaches are drowned; otherwise they must be killed by scalding, burning, oiling or otherwise.

The croton bug is more wary than the larger forms, and can crawl up the sides of a glass jar. A dark box trap with one or more tubular pasteboard entrances projecting both inside and outside is preferable. The inside mouth of the tube must be fitted with a trap door or adhesive substance around the outside of the tube to prevent the roaches from escaping. The bait may be sugar, sweet chocolate or the like. Captured roaches are shaken out into kerosene or hot water.

Borax and sodium fluoride are poisonous to these insects. Equal parts of chocolate or powdered sugar and borax, well mixed (this is important), is one form of a roach powder. This powder should be placed in little heaps, in accessible windows, or in the crevices whence the insects come.

According to Farmers' Bulletin 648, U. S. Department of Agriculture, the most effective material is 50 per cent commercial sodium fluoride mixed with some inert substance, such as powdered gypsum or flour. Marlatt recommends that such a mixture be dusted or blown over shelves, tables, floors and the runways and hiding places of roaches. The insects come out, and die in a few hours. In this way complete extermination is effected within twenty-four hours. Such repellents as eucalyptus oil, oil of citronella, oil of rosemary, and naphthalene may be used where other methods are undesirable. Fumigation with hydrocyanic acid gas, carbon bisulphide or sulphur is successful, but should not be undertaken without experience.

California March Examination

Dr. Charles B Pinkham, secretary of the California Board of Medical Examiners, reports the written examination held at Los Angeles, March 8-11, 1926. The examination covered 9 subjects and included 90 questions An average of 75 per cent was required to pass. Of the 63 candidates examined, 51 passed and 12 failed. Sixty-six candidates were licensed by reciprocity and 6 by endorsement of credentials since the February meeting of the board. The following colleges were represented:

Book Notices

LES TUMEURS DU CERVEAU. Par le Professeur Viggo Christiansen, Medecin en chef de l'Hôpital royal du Danemark Avec une preface du Pr Pierre Marie Second edition Paper Price, 45 francs Pp 398, with 107 illustrations Paris Masson & Cie, 1925

This edition is dedicated to the memory of Charcot. The author states that there have been so many advances in our knowledge of the symptomatology, diagnosis and surgical treatment of intracranial new growths that the book had to be entirely rewritten Epidemic encephalitis, which is now so prevalent, sometimes simulates brain tumor, and the differential diagnosis between new growth and encephalitis had to be fully considered As in the previous edition, the subject matter is presented in the form of lectures, which does not make for dry reading in this instance. The style is clear and simple, and the descriptions are lifelike. Especially illuminating and instructive are the discussions of the significance of special symptoms and the frank acknowledgment of errors in diagnosis and failures in therapy. Three chapters are devoted to tumors of the motor region In paralyses of cerebral origin, the lower is often not as much affected as the upper extremity, because compensation from the other side occurs more often in the leg than in the arm The sternomastoid, on account of its bilateral innervation, is often unaffected, while the trapezius is usually paralyzed. Attention is called to the fact that only one group of muscles or even a single muscle may be involved, and that muscle atrophies are frequent in cortical lesions. In tumors of the occipital lobe, the representation of macular vision is not localized but extends over a considerable area in each lobe. Migraine ophthalmique is especially considered in relation to tumors of the base of the brain, and the differentiation between basilar tumors and syphilitic basilar meningitis is often difficult. The chapters devoted to tumors of the chiasmatic region and of the cerebellopontile angle give an excellent summary of our present knowledge of the symptoms of growths in these locations. The roentgen ray often does not show the extent of the changes that exist in pituitary tumors. One eye is often blind when the other still has only a defect in the temporal field of vision. Papilledema is not at all rare in pituitary growths, and may conceal a certain amount of primary optic atrophy. Christiansen believes that papilledema in pituitary tumors may be due not to a general increase of intracranial pressure but to direct pressure on the arteries and veins in the neighborhood of the growth. The chapter devoted to "difficulties in diagnosis" is worthy of careful reading, for it is a fair statement of the diagnostic problems so often encountered, and of the various methods of value for the localization of the growth. In the chapter on operative treatment, technical surgical details are not considered. Decompressive operations often give considerable palliation, but the only real successes are obtained in those cases in which the tumor can be completely removed. Whenever possible, the operation should be done in one stage, and the best results are obtained by those who have devoted themselves as specialists to neurologic surgery. The subject of tumors of the brain is so large that a book on the subject might easily be a large and ponderous volume; but Christiansen has demonstrated how much can be said in a few words when the writer is expert in the recognition and evaluation of clinical symptoms and signs.

ABDOMINAL OPERATIONS. By Sir Berkeley Moynihan. Fourth edition. Two volumes. Cloth. Price, $20 net. Pp. 1217, with 470 illustrations. Philadelphia: W. B. Saunders Company, 1926.

As in previous editions, the bulk of the material is devoted to the stomach, intestines and bile tracts. To detail the contents would be needless; they are too well known to surgeons. There are places where one may take issue with Moynihan. Even today surgery at its best is too frequently a conflict of ideas on the application of mechanical skill in the adjustment of anatomic derangement and malfunction, so a surgeon may justify an arbitrary or dogmatic attitude by logic and by brilliant results. This work is for the most part an exploitation of the author's own opinions and technic, and one reads under the spell of his personality. His ideals are of the highest:

> If I might presume to offer any advice to the surgeon who has not great and continued opportunities for practical work, I would suggest to him never to do gastro-enterostomy in the absence of a demonstrable lesion which requires it, and to leave the surgery of the gallbladder alone. No one acquainted with the truth can deny that far too many operations nowadays are done by those who having perhaps a measure of success in the trivial cases (none are trivial to a patient!) rashly embark on procedures which they are not fully competent to undertake. Surgery, after all, is an affair of the spirit; it is a fierce test of a man's technical skill sometimes; but in a grim or long fight it is above all a trial of the spirit, and there are few things that cannot be conquered if a man's heart is set on victory.

The teachings are those of a master surgeon written in a style that upholds the best traditions of English prose.

TUMORS OF THE COLON AND RECTUM: Their Pathology, Diagnosis and Treatment. By Jerome M. Lynch, M.D., Surgical Director, St. Bartholomew's Hospital, N. Y., and Joseph Felsen, M.D., Attending Pathologist, St. Bartholomew's Hospital, N. Y. Cloth. Price, $12. Pp. 259, with 123 illustrations. New York: Paul B. Hoeber, Inc., 1925.

This is a monograph de luxe, a tale built about beautiful illustrations, for about one fifth of the pages are solely illustrations, really plates, many in colors, making the work quite like an atlas. And with these there are many other fine illustrations. There is a great similarity between the gross and microscopic appearance of some of the different tumors illustrated, more, of course, in their histology, for they are uniformly cylindric-cell carcinomas, called by the authors adenocarcinomas, and for much of this repetition there is no valid excuse. It may occur, indeed, that in the course of time the use of "malignancy" for malignant tumor will conform to the best usage. Its employment, as indicated, is prevalent. But the conception of malignancy includes many characteristics, such as rapid growth, the production of a cachexia, recurrence and metastasis; and to refer to a "malignancy of the descending colon," or of any other part of the colon (pp. 200, 201 and 202) or, for that matter, of any part of the body seems to restrict the term to purely objective significance, to rob it of much of its time-honored value. Anthrax causes a malignant pustule of the bowel, and still other lesions are referred to as malignant. When a malignant tumor is meant, the statement should be malignant tumor, and not "malignancy." Naturally, most of the experience set forth by the authors has concerned carcinoma of the colon, but there is a good review of other tumors of the colon. The bibliography, indexes and many tables, especially those devoted to the results of treatment (4,013 cases), are all excellent. The work is a commendable record of research in surgery of value for reference, for libraries and for the private libraries of surgeons.

CHEMISTRY IN MODERN LIFE. By Svante August Arrhenius, Ph.D., M.D., D.Sc., Director of the Nobel Institute. Translated from the Swedish and revised by Clifford Shattuck Leonard, Ph.D., National Research Fellow, Department of Pharmacology, Yale University. Cloth. Price, $3. Pp. 286, with illustrations. New York: D. Van Nostrand Company, 1925.

Professor Arrhenius, director of the Nobel Institute, and recognized throughout the world as one of the great modern leaders in the field of chemistry, prepared this interesting introduction to his science for Swedish readers. The translation is made available as a part of the library of modern sciences. The book covers briefly all of the relations of chemistry to life, to industry and to the home. The historical background is introduced painlessly, and illustrations from life add to the human interest of the work. The book is an excellent presentation volume for the young man or woman interested in this field.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

DIE BEDEUTUNG DER ROTEN KERNE UND DES ÜBRIGEN MITTELHIRNS FÜR MUSKELTONUS, KÖRPERSTELLUNG UND LABYRINTHREFLEXE. Von Dr. G. G. J. Rademaker. Monographien aus dem Gesamtgebiete der Neurologie und Psychiatrie. Herausgegeben von O. Foerster und K. Wilmanns. Heft 44. Paper. Price, 27 marks. Pp. 340, with 212 illustrations. Berlin: Julius Springer, 1926.

Monograph on brain physiology with especial reference to the red nucleus.

THE X-RAY IN EMBRYOLOGY AND OBSTETRICS. By W. A. Newman Dorland, A.M., M.D., F.A.C.S., Professor of Gynecology and Obstetrics and Head of the Department of Obstetrics in the Post-graduate Medical School of Chicago, and Maximilian John Hubeny, M.D., F.A.C.R., F.A.C.P., Editor of Radiology. Cloth. Price $10. Pp. 420, with 259 illustrations. Saint Paul: Bruce Publishing Company, 1926.

Beautifully illustrated volume on special roentgenologic study.

HANDBUCH DER HALS-NASEN-OHREN-HEILKUNDE. Herausgegeben von A. Denker und O. Kahler. Sechster Band. Die Krankheiten des Gehörorgans. Erster Teil. Anatomie. Entwicklungsgeschichte. Physiologie. Pathologie. Untersuchungsmethoden. Therapie. Paper. Price, 96 marks. Pp. 1274, with illustrations. Berlin: Julius Springer, 1926.

Sixth volume of monumental system of diseases of ear, nose and throat.

DIET LISTS OF THE PRESBYTERIAN HOSPITAL, NEW YORK CITY. By Herbert S. Carter, A.M., M.D., Consulting Physician to the Lincoln Hospital. Third edition. Cloth. Price $2. Pp. 173. Philadelphia: W. B. Saunders Company, 1926.

Practical and complete outline of established diets for all conditions in which dietetic management is established.

Les problèmes de la physiologie normale et pathologique de l'os. Par R. Leriche, Professeur de clinique chirurgicale à la Faculté de Strasbourg, et A. Policard, Professeur d'histologie à la Faculté de Lyon. Paper. Price, 28 francs. Pp. 229, with 29 illustrations. Paris: Masson et Cie, 1926.

Monograph on pathology of bone.

Diätetik der Magen- und Darmkrankheiten. Von Prof. Dr. I. Boas. Diätetik und Nachbehandlung bei Operationen am Magen-Darmkanal. Von Prof. Dr. G. Kelling. Second edition. Paper. Price, 12 marks. Pp. 242, with 19 illustrations. Leipsic: Georg Thieme, 1926.

Second edition of standard work on dietetics in gastrointestinal disease.

The Technic of Nursing. By Minnie Goodnow, R.N., Directress of Nurses, Hospitals of the Graduate School of Medicine, University of Pennsylvania. Cloth. Price $2.50 net. Pp. 452, with 207 illustrations. Philadelphia: W. B. Saunders Company, 1926.

Another book of helpful hints for nurses who have to practice medicine.

Emergency Surgery: The Military Surgery of the World War Adapted to Civil Life. By George de Tarnowsky, M.D., F.A.C.S., D.S.M., Professor of Clinical Surgery, Loyola University Medical School. Cloth. Price $7.50. Pp. 718, with 324 illustrations. Philadelphia: Lea & Febiger, 1926.

Practical help in surgery for the general practitioner.

Les races et les peuples de la terre. Par J. Deniker, Docteur ès sciences, bibliothécaire du muséum d'histoire naturelle. Second edition. Cloth. Price, 65 francs. Pp. 750, with 340 illustrations. Paris: Masson et Cie, 1926.

New edition of work on general anthropology first issued in 1900.

Chirurgie du sympathique. Chirurgie du tonus musculaire. La section des rameaux communicants. Par P. Wertheimer, et A. Bonniot, Chirurgien des hôpitaux de Grenoble. Préface du Pr. Leriche. Paper. Price, 22 francs. Pp. 134, with 21 illustrations. Paris: Masson et Cie, 1926.

Technical monograph on sympathectomy.

Massage und Gymnastik im Dienste der Kosmetik: Beiheft zum Handbuch der Massage und Heilgymnastik. Von Dr. Fr. Kirchberg, Lektor für Massage und Heilgymnastik an der Universität Berlin. Boards. Price, 3.90 marks. Pp. 99 with 26 illustrations. Leipsic: Georg Thieme, 1926.

Massage for wrinkles and fat removal.

Troubles des échanges nutritifs; physiologie-pathologie-thérapeutique. Volumes 1 and 2. Par Ch. Achard, Professeur de clinique médicale a la Faculté de médecine de Paris. Paper. Price 110 francs. Pp. 1220, with illustrations. Paris: Masson et Cie, 1926.

French consideration of general metabolic disturbances.

Right to Results of Laboratory Analysis of Organs

(Travelers' Ins. Co. v. Jackson, Judge (Iowa), 206 N. W. R. 98)

The Supreme Court of Iowa says that, in an action on a policy of accident insurance which expressly excluded liability for death by suicide, the insurance company averred that the death of the insured resulted from suicide. A necropsy on the body was conducted by two physicians selected by the plaintiff in that case and by two other physicians selected by the insurance company, all of whom acted in cooperation. Then the two physicians representing the company took certain organs from the body for a laboratory analysis, it being averred on one side, and denied on the other, that those physicians agreed that the results of the analysis should be communicated to the physicians for the plaintiff. That the plaintiff subsequently obtained from the district court an order that the insurance company should produce and furnish to the plaintiff "all papers, findings, records, entries and memoranda of laboratory analyses and inspection of the tissues and vital organs" of the insured, in its possession or under its control, as would tend to show that his death was due to an accident. That order was made under the provision of section 4654 of the Iowa code that the district court may in its discretion, by rule, require the production of any papers or books which are material to the just determination of any cause pending before it, for the purpose of being inspected and copied by or for the party calling for them. The legality of the order made was challenged in this proceeding, by certiorari, to test it.

The only showing in support of the application for the order was that there had been a laboratory analysis. Perhaps it ought to be assumed that such laboratory analysis would contain many details which could be safely preserved only by committing them then and there to paper. There was no showing that there was in existence any other paper, record or finding which could in any manner serve any purpose to the applicant as material and admissible evidence. It was, however, suggested, and assumed in argument, that the two physicians who represented the insurance company had communicated, perhaps by letter, with the company, and had expressed opinions including doubts on various features of the necropsy and of the laboratory analysis. No reason was apparent why such sweeping terms should be used in the order unless they were intended to include all communications by such physicians to their own employer on the subject under consideration. Manifestly, such "papers" would not be admissible in evidence. It might be that if the necropsy disclosed all the vital organs to be normal and healthy, such fact might be material and proper to be considered in connection with other facts tending to show accidental death. But that the applicant was not entitled to the production of private letters, or communications, or memoranda, or opinions, or findings, by the two physicians to the insurance company as their employer, was quite clear. None of such items would be admissible as instruments of evidence, though the applicant might gain practical advantages in the trial of the case, because of their perusal. The statute, however, cannot be used to such an end. To say the least, therefore, the order was too broad.

Could the direct results of the laboratory analysis be deemed a "paper" within the meaning of the statute? Must it be assumed that those results were committed to paper? As against this, it was to be said that both parties in the presentation of their case here had assumed that the results of the analysis were committed to paper, and that this was furnished to the insurance company. In view of the fact that the results of the laboratory analysis would be material on the trial, and that they would be provable in some manner, and that the insurance company had the exclusive access to them, and that no other analysis was practicable, the supreme court is disposed to solve the doubt in favor of the order of the trial court at this point, and to let the order stand so far as it relates to the direct results of the laboratory analysis.

The order will be modified so as to require the insurance company to furnish a copy of the direct results of the laboratory analysis, and to exempt it from furnishing private correspondence or memoranda or expressions of opinion as between it and the physicians employed by it. To this extent the order of the district court will be annulled, and in all other respects affirmed.

Eye Made Not to Coordinate with Other Counted Lost

(Suggs v. Ternstedt Mfg. Co. et al. (Mich.), 206 N. W. R. 490)

The Supreme Court of Michigan says that the plaintiff, by an accident that arose out of and in the course of his employment, received an injury by a particle of steel becoming embedded in his right eye. As a result of the injury, a traumatic cataract formed, which was removed by an operation. After the operation he had one-sixtieth normal vision without the use of a glass, while with a strong glass his vision with that eye was above normal, but his two eyes did not coordinate. If he used the uninjured eye, he could not wear the strong glass on the other. If he used the injured eye with the strong glass, he had to cover the other eye. In other words, the testimony established that, while he had useful vision with each eye, he could use but one of them at a time. Under these circumstances the department of labor and industry held that he was entitled to the statutory compensation for the loss of an eye, and the award which it granted is affirmed by the supreme court.

What Expert Testimony Should Do—Injury to Vision

(City of Kingfisher et al. v. State Industrial Commission et al. (Okla.), 242 Pac. R. 217)

The Supreme Court of Oklahoma, in affirming an award of compensation made by the industrial commission, says that the claimant while in the employ of the city of Kingfisher as assistant engineer in the water works department had some boiler compound of soda, ash and lime splash out of a tank into his face and right eye, injuring his vision. Very much of the expert evidence in the case was conflicting, inconsistent and unintelligent. Expert testimony should serve the purpose of making clearer to the ordinary mind facts that are obscure and understood only by scientific study, skill and experience, and such testimony should be definite and certain, and explanatory of the point under consideration.

With regard to compensation under the workmen's compensation law of Oklahoma, the court holds that where the injured employee has lost all practical use of an eye as a result of an injury, such employee is entitled to compensation irrespective of his ability to continue to perform the work in which he was engaged at the time of his injury. The test as to the rights of an injured employee to receive compensation is dependent only on his having received an accidental personal injury resulting in such a permanent partial disability as is provided for in the schedule of the compensation law.

Diseased "Alien Seamen" to Be Treated in Hospitals

(United States v. New York & Cuba Mail S. S. Co. (U. S.), 46 Sup. Ct. R. 114)

The Supreme Court of the United States holds that the term "alien seamen" means seamen who are aliens, as it is used in the act of 1920, which provides that alien seamen found on arrival in ports of the United States to be afflicted with any of the disabilities or diseases mentioned in section 35 of the Alien Immigration Act of 1917, including any loathsome or dangerous contagious disease, shall be placed in a hospital designated by the immigration official in charge at the port of arrival and treated, all expenses connected therewith to be borne by the owner or master of the vessel; and that where a cure cannot be effected within a reasonable time the return of the alien seamen shall be enforced on or at the expense of the vessel on which they came. In other words, the term "alien seamen" means, not seamen on foreign vessels only, but aliens employed as seamen on any vessel arriving in the United States; and it was intended to extend the provisions of section 35 by providing that the hospital expenses incurred in treating any such diseased alien should be borne in all cases by the vessel bringing him in, whether carrying passengers or freight, and without reference to the time when the disease might have been detected. Nor, when applied to American vessels, is the act as thus construed repugnant to the due process cause of the fifth amendment to the constitution, on the ground of imposing liability without causation or causal connection. The power of Congress to forbid aliens and classes of aliens from coming within the borders of the United States is unquestionable. This power may be exercised in reference to alien seamen as well as other aliens, and if they are found to be diseased when brought into an American port, the vessel, whether American or foreign, may lawfully be required to bear the expenses of their medical treatment.

Competence of Physician to Give Opinion on Sanity

(Commonwealth v. Cavalier (Pa.), 131 Atl. R. 229)

The Supreme Court of Pennsylvania, in affirming a judgment of conviction of the defendant of murder in the first degree, says that the defense attempted to be made for him was that he was mentally incompetent and insane at the time of the killing. To meet that defense the commonwealth called, among other witnesses, a physician who, in answer to a hypothetic question, gave it as his professional opinion that the defendant knew the nature and quality of his act, and could distinguish between right and wrong. It was urged that the physician was not competent to express an opinion. He was a practicing physician, a graduate of the University of Pennsylvania, and at the time of the trial had been engaged in the practice of his profession for between four and five years. He was at no time connected with an institution having for its main purpose the treatment of mental disease, and had not seen many cases of insanity. He had as a part of his medical education studied the subject of insanity, and would appear to have at least the general knowledge of the subject that the ordinary medical practitioner has. The question of the competence of a witness to testify as an expert is usually for the discretion of the trial court, and the supreme court is not convinced that there was an abuse of discretion in receiving the testimony. It would be an impracticable thing to lay down a hard and fast rule as to how much experience a practicing physician must have had with insane persons to qualify him to speak as an expert. The supreme court thinks that the determination of this question is wisely left with the trial judge, who has the witness before him, and is better competent than the supreme court is to judge of his capacity to express an opinion. The weight to be given his opinion is, of course, for the jury.

Action for Not Properly Furnishing Treatment Barred

(Chalmers v. Southern Pac. Co. (U. S.), 8 Fed. R. (2d) 480)

The United States Circuit Court of Appeals, ninth circuit, in affirming a judgment of nonsuit, says that the complaint stated that while the plaintiff was in the employ of the defendant and it was under contract, in consideration of a payment by him of 75 cents a month, to furnish him with medical and surgical treatment in case of injury, he suffered an injury and by reason of the defendant's failure to use roentgen-ray appliances to diagnose the broken bone the treatment furnished proved valueless. The question presented for consideration here was the character of the action. Whatever might be said of the cause of action disclosed by the complaint, the court saw no escape from the conclusion that the cause of action disclosed by the testimony was an action ex delicto (for a wrongful act or neglect), within the meaning of the statute of limitations of the state of California, as construed by its highest court, because under the testimony the alleged breach of contract consisted, not in a failure or refusal to furnish medical and surgical treatment or hospital care and attention, but in a failure to furnish medical and surgical treatment with due care and in a proper manner. Therefore, under the settled rule in California, the cause of action disclosed by the testimony was barred after one year by the statute of limitations.

ASSOCIATION OF AMERICAN PHYSICIANS

Forty First Annual Meeting, held at Atlantic City, N J, May 4 5, 1926

(Continued from page 1862)

The Circulation and Its Measurement

Dr. H W. Haggard, New Haven, Conn: In this study we tried to find out what reserve the heart might have. We took fifty students, many of them good athletes We first measured the stroke index; but this is disturbed by the pulse, which shows variations during effort. One man rode a bicycle till he fell off, at first the pulse went up, and later fell. There are two compensatory mechanisms affecting this: 1. Value of the heart as a pump 2 The amount of oxygenation of the blood We find that the output of the heart remains the same at rest as in exercise There is an increase up to the maximal point, but this cannot be raised. When we measure the amount from the resting point to the maximal output, we find that the best heart has the largest range. There is an increased oxygen consumption of 3,400 per minute, which is the greatest increase from resting The man with the greatest increase in oxygen consumption has the best heart. The best rate showed an increase of five and one-half times from resting, the worst man had an increase of two. This is the difference in the grading of men as regards cardiac reserve

DISCUSSION

Dr G Canby Robinson, Nashville, Tenn: The blood flow is diminished when patients sit up, and further diminished when they stand. We are accustomed to believe that the circulatory effect has something to do with diminished output of the heart Patients improve when they assume a sitting position, so we can say that patients improve when the output is actually diminished. We have studied the output of the heart under the influence of digitalis in animals, using the Trick method. The output is about 25 per cent less Here we have some evidence that the circulation may be improved when the outflow of the heart is increased. I believe that the balance between the two sides of the heart is more readily adjusted when the heart is putting out less blood than when there is increased amount of blood

Dr B S Oppenheimer, New York: We have been measuring blood flow by the method of Henderson and Haggard, in twenty-one normal subjects and sixteen cases of valvular disease, and in hypertensive disease with and without auricular fibrillation. In the normal cases the results were sufficiently consistent to be satisfactory. They agreed with the Henderson and Haggard figures. In the cardiac cases, the results were consistent, but there is a certain degree of dyspnea in most cases. There was reduction of the outflow per minute, with smaller output per day. There was also increase of consumption of arterial oxygen.

Dr. Charles F. Hoover, Cleveland: In cardiac patients with retention of body fluids, the clinician has difficulty in demonstrating where the accumulation of blood may be, where the failure in hydraulics of the circulation occurs. Cardiac failure and failure in hydraulics are not the same thing. We have seen patients with great respiratory distress make very satisfactory progress, but we could not prove any difference in volume flow. We tried studying heat loss by air from the lung, but there was no evidence of genuine hydraulic failure. We must differentiate between circulatory failure and hydraulic failure.

Blood Flow During Rest and Exercise in Normal Man

Drs. A. V. Bock, L M. Hurxthal, J. F. Lawrence and D. V. Dill, Boston: We have made a special study of the work of the heart during rest and exercise. There is a remarkable shift of blood being pumped from the heart with change of position. When the subject sits in a chair the blood flow drops from 20 to 30 per cent from the prone position, and on standing there is a drop of from 40 to 50 per cent. These changes account, perhaps, for the feeling of fainting or dizziness both in the well and in the sick. The pulse pressure is completely lost when the subject faints. In our tests we have had the subjects standing at attention in a rigid upright posture. The standing position is necessitated by gravity for returning blood to the right side of the heart, and the vital capacity is increased from 6 to 8 per cent when standing. In cardiac cases there is a change of from 25 to 30 per cent when the patient is standing; thus, the change is much increased in the cardiac patient. This is at variance with the old theory that the vitality capacity is a mechanism purely related to the movement of the costal muscles. In regard to the reactions of the body to exercise, determinations of the blood flow in patients on a stationary bicycle were made, the work being 15 miles an hour, pulling 9 pounds weight. There were 15 liters a minute increase in blood flow. The oxygen consumption per minute and blood flow were increased with increased metabolism. We found that there was a steady coefficient of utilization of oxygen up to 1,200 cc. of blood The pulse rate bears relation to the total ventilation curve. We found that the amount of oxygen taken out of the inspired air is definitely limited, and the same thing is true of the amount of carbon dioxide utilization. The body seems to make an effort to keep the percentage of carbon dioxide in the body at a constant figure. There is at present considerable mystery as to what is back of the maximum of respiration, that is, what is keeping the body in a steady condition of carbon dioxide elimination.

Clinical Physiology of the Stomach

Drs A L Bloomfield and C. S. Keffer, Baltimore: We have made studies of the pure gastric juice with its hydrogen ion content in gastric motility. First we did an estimation of the secretion during a ten minute period in different individuals We found differences of from 10 to 70 cc. of juice in ten minutes, and in normal persons it varies from 10 to 40 cc The total acid of the pure juice varies from 120 cc to zero. We found no reason to believe that the total acid was less normal at 20 than when it was 60. We expected that there would be a relation between the volume of secretion and the degree of acid, but there is no relation at all There was no relation found between the volume of the secretion and the total volume of fluid and the emptying of the stomach. Some stomachs empty very quickly. The emptying time of the stomach varies from fifteen to ninety minutes The emptying of the stomach presented no relation to the acid content Persons were examined under basal conditions with repeated observations to see whether they were more or less constant from week to week. It was found that curves corresponded very closely in the same subjects The amount of acid is a constant feature. The volume of secretion is fairly constant. The motility has great variation in the same subject on different occasions.

DISCUSSION

Dr W E. Dixon, Oxford, England: The point of view of physicians is that the contents of the duodenum are passing to the stomach and back from the stomach to the duodenum. It can be proved that the amount of acid varies from time to time, within a few minutes when there are two tubes in different parts of the stomach. Different degrees of acidity and different degrees of digestive power can be observed. The old idea that the acid of the stomach has to do with the pancreas is entirely wrong.

Dr A. L. Bloomfield, Baltimore: The matter of bile regurgitation was absolutely controlled in these subjects. Although these volumes were passed in ten minute intervals, the study of the secretion was done over an hour or more on the stomach; therefore the studies show that the secretion is more constant.

So-Called Lipoid Nephrosis

DRS. LOUIS M. WARFIELD and F. D. MURPHY, Milwaukee: The "large white kidney" has been described for many years. It has been found that tubular lesions were not due to inflammatory degeneration. Some observers, however, believe that the cases are preceded by glomerular nephritis, but it is not really proved whether glomerular nephritis precedes or follows. The disease is insidious. It is usually seen in young persons; it begins with headache and malaise, but kidney function is good. The urine shows crystals (doubly refracting lipoids), probably cholesterin esters. We feel that the lesion in these cases has something to do with the colloid metabolism of the body. The cases go from onset to death without any inflammatory symptoms. Probably it is not the result of a chronic inflammatory lesion, but lipoid degeneration of the kidney may follow glomerular nephritis. A characteristic of these lipoid nephroses is the edema, which is fluctuating and does not seem to be influenced by treatment. We did not get much result from thyroid treatment, but it has some effect. *The prognosis in these cases is fairly good.* The differentiation between pure lipoid nephrosis and glomerular nephritis with secondary degeneration of the tubules is often diffcult. We have a patient under observation who had an attack of glomerular nephritis last September. At present he is in a quiescent stage. The kidney function tests show normal fluid. The blood cholesterol is high. Doubly refracting lipoids have not been found yet, but we shall find them soon. This type of case has been confused with pure lipoid nephrosis. The characteristic feature is the periodicity of the edema. The diagnosis of these conditions does not depend on any test, but is based on fulfilment of the reactions enunciated by us and on the findings of those who have followed the disease through its course to the postmortem examination.

DISCUSSION

DR. D. VAN SLYKE, New York: We have had cases that have had every characteristic of Dr. Warfield's cases, with good function and normal blood pressure, intense albuminuria, that seem to be in every way typical of pure lipoid nephrosis. The patients gradually develop urea retention, and two have died from characteristic uremia. I do not know whether these cases started as a pure nephrosis or whether they were cases of acute glomerular nephritis. This may be the secondary stage. Nephrosis, perhaps, may be expected to follow kidney insufficiency, uremia.

DR. J. P. O'HARE, Boston: There are two points worthy of emphasis. There are two ways of making a diagnosis. In subacute glomerular nephritis there is a similar sediment with red blood cells, yet not small round tubule cells. In uncomplicated nephrosis, there are no cells at all and but rarely red blood cells. Nephrosis of this type ordinarily reacts better to diuretics such as calcium than does glomerular nephritis.

DR. LOUIS M. WARFIELD, Milwaukee: I do not know how to make the diagnosis, except to follow the cases a long time. When there are red blood cells in the urine, it cannot be a pure case of nephrosis, but has an inflammatory condition added.

Results of Thyroidectomy for Hyperthyroidism as Indicated by Examination a Year or More Following Operation

DR. CHARLES A. ELLIOTT, Boston: Severe hyperthyroidism is a progressively injurious disease and should be controlled. A subtotal thyroidectomy stopped symptoms in seventy-one out of seventy-four hyperthyroid cases; three patients were myxedematous. There was permanent visceral injury in forty-seven out of sixty-four cases, and thirty-seven cases with residual injury. In twelve patients, permanent disability was evident.

DISCUSSION

DR. JOSEPH L. MILLER, Chicago: I should like to ask whether Dr. Elliott noticed any deleterious effects from the use of iodine in any cases of toxic adenoma.

DR. N. B. FOSTER, New York: I should like to confirm one observation, and that is that we occasionally see favorable results following iodine administration in toxic adenoma. Occasionally cases respond to thyroxin, which should make them worse.

DR. W M. BOOTHBY, Rochester, Minn.: Dr. Elliott's report agrees in the main with the experience of many of us. His report of improvement with iodine in the adenomatous goiter is larger than we obtain. The differential diagnosis varies in different places. On the more strict classification of the adenomatous goiter, the reports of improvement of cases of adenomatous goiter will be less than if the classification is made on a more liberal basis. If they have symptoms characteristic of the disease they are almost invariably controlled On the other hand, adenomatous goiter with hyperthyroidism is not predictable, and the case may or may not be made better with iodine; it may be made worse. There is one other guide, an important point which must be remembered in making postoperative observations, and that is the question of parathyroid insufficiency. We are beginning to observe this in the postoperative studies of maximal subtotal thyroidectomies; there is a more frequent occurrence of permanent parathyroid insufficiency. There is developing what we should recognize as a new syndrome. We have seen nothing like it before. This syndrome is often confused with a myxedematous syndrome, while there is no real myxedema. There are no obvious symptoms of tetany. The tetanic symptoms have been adjusted, yet the essential picture is one of weakness and plastic immobility.

DR. CHARLES A. ELLIOTT, Boston: I give iodine in the exophthalmic goiter cases with the certainty of getting results and knowing that the metabolic rate will go down. Then we feel that operation is a safe procedure. In the toxic adenomatous group we give iodine under careful observation, realizing that some of these patients are apparently made worse. I was surprised in adding up the figures in this small group to find that there was very little difference in the response to iodine in the two groups. I said nothing about postoperative tetany. We have noticed that, especially in the last six months. The cases so far have been mild and respond to the specific hormone. We do not know what the ultimate outcome may be. So far as the use of iodine during the postoperative period is concerned, the experimental work of Narine has justified us in the assumption that hyperplasia of the thyroid does not occur readily in the presence of iodine; therefore one method is the routine giving of iodine postoperatively.

Hypothyroidism as a Cause of Intractable Constipation

DR. THOMAS R. BROWN, Baltimore: In patients with intractable constipation, with sluggishness in motility, increase of weight, and in whom a resection of the colon seems to be the only mode of relief, we have suggested the use of thyroid extract, 6 grains (0.4 Gm.) daily, continued for as long a time as is needed to relieve the symptoms entirely. We have studied the influence of thyroid function on intestinal motility, and have made 199 readings in two years. The majority of the patients were women in the fourth to sixth decades of life. Digestive disturbance and constipation were the chief complaints. In half of these patients the basal metabolic rate was from — 10 to — 19. A few had hyperthyroidism. Cases occurring in more than one member of a family suggested a familial relation. The symptoms usually included more or less mental dulness, darkness of the skin, mental fatigue and digestive disturbance. Most of these patients had been told that they had intestinal toxemia. All but three had marked constipation. In nine it was intractable. Roentgen-ray examination showed that the position of the stomach and colon was normal. Small doses of thyroid extract seemed to have a beneficial effect; in the intractable cases it seemed to be the only thing that produced effect. Constipation returned when the drug was stopped; therefore it was found that it should be continued indefinitely. The dose was from one-fourth grain to 6 grains (from 0.016 to 0.4 Gm.) daily.

Compression Sounds of Korotkov.—Contributory evidence is brought forward by Korns in support of the reasonable assumption that the mechanism which operates to produce the Korotkov sounds in man is identical with the water hammer action that Erlanger has found to be the cause of arterial sounds in animals. Furthermore, it is demonstrated that initiation of the hydraulic impact of water hammer is characterized by sound vibrations of relatively short period. The general similarity of the vibrations at all levels of decompressing pressure indicates that the Korotkov sounds originate in an impact at one fixed spot. There is no evidence that eddies or whorls contribute to sound production. Division of the Korotkov sounds into so-called "phases" seems unwarranted. It is suggested that in this respect the clinical conception of the sounds is in need of revision.

Formation of Bile Pigment from Hemoglobin.—The investigations made by Mann et al. have proved that: Bilirubin is formed in the spleen and marrow; it is formed from hemoglobin; hematin appears as an intermediate product in the formation of bilirubin from hemoglobin.

Hydrogenated Vegetable Oil Source of Vitamin E.—Kennedy and Palmer show that successful reproduction can be secured in three successive generations of rats on the Evans and Bishop sterility diet when lard is replaced by hydrogenated vegetable oil. It may be inferred from these observations that hydrogenation does not destroy the fertility factor, vitamin E.

Diet and Reproduction.—It appears to Nelson et al. that data are by no means conclusive for the existence of unknown dietary factors for reproduction and milk secretion.

Study of Hunger Contractions.—Rogers and Martin observed that the type I hunger contractions of Carlson's classification are essentially strong circular contractions of the lower half of the stomach, involving particularly a band of muscle near the junction of the middle and lower thirds of the stomach. This type of hunger contraction may or may not be associated with active peristalsis. Type III contractions consist of active peristaltic waves running over a hypertonic stomach.

Roentgen-Ray Signs of Chronic Gastritis.—The lesser and greater curvatures of the stomach are in regular outline even when the peristaltic waves are active in the properly fitted, normal stomach. Bassler finds that, in well-established chronic gastritis, the regular line is much changed in appearance, as some of the ulcerated states of the left colon and sigmoid testify. Often in chronic gastritis, numerous small indentures and bulgings, none of them much more than a centimeter in depth or height, are seen along the greater curvature, but only occasionally along the lesser. With this the whole stomach displays a lack of regular, large, sweeping peristaltic phenomena—the waves, when of some size, being irregular and in other instances the whole organ being bag-like and inactive as far as normal peristalsis is concerned. This serration of the greater curvature outline may be definitely localized such as in the pyloric region and at the base of the cap, or, as is most often seen, in the lower two thirds of the greater curvature. The third important point in the finding is that the irregularity of the lower outline is noted only in the films or observations made in the prone position and is completely obliterated in those made in the upright. Bassler's explanation of this phenomenon is that in organic disease of the mucosa of the stomach, when deep enough to comprise involvement well into the mucosa, the fibrils into it from the nervous plexus under it are cut off or the function distributed so that normal peristaltic phenomena are interfered with. Instead, then, of stimuli passing along through the stomach walls in succession of stimulation and inhibition, thus producing the large and regular normal peristaltic waves, the whole mechanism is thrown out of regularity and the waves are made hectic and local only here and there. The latter are mostly brought about by lack of proper passing of stimulation in a circular way around the organ, producing in a transverse line across the stomach the phenomena of contraction, dilatation and inactivity on the line in different locations. The interference with the proper nerve function likewise diminishes the power of such waves as are present, thus making the organ more bag-like, which, when the disease of the mucosa is general, increases the capacity of the organ (dilatation) but does not do this if the catarrhal process is localized such as in the pyloric region.

Treatment of Partial Deafness.—Clinical experience in a fairly large series of cases has demonstrated to Hollender and Cottle that electrophysical therapy is of some value in chronic catarrhal deafness even after other accepted measures have failed. The improvement obtained is dependent on four important factors: (1) nature and extent of pathologic change; (2) correct apparatus and electrodes; (3) proper application based on anatomic principles; (4) persistent treatment over a long period of time.

Local or Tissue Immunity. F. P. Gay, New York.—p. 590.

Bilateral Carotid Arteritis.—A case of bilateral carotid arteritis with thrombosis is described by Harbitz, and the question is raised whether it concerns a distinct form of arterial disease.

Granuloma Venereum.—Seven cases of granuloma inguinale have been studied by Goldzieher and Peck. An organism that is biologically and morphologically identical has been observed in all cases. Pure cultures were obtained in five cases. The etiologic agent of venereal granuloma is termed *Bacillus venereogranulomatis*—a proper genus of the family *Bacteriacae*. The etiologic rôle of the organism described is supported by the results of complement fixation, allergic tests and animal experiments.

Congenital Sarcoma of Tibia.—Kolodny reports a case of congenital sarcoma of the tibia occurring in a girl, aged 8 weeks. A high thigh amputation was made. The patient is now 8 years old, well and without evidence of a recurrence or metastases.

Familial Juvenile Cirrhosis of Liver.—A case of cirrhosis of the liver occurring in a girl, aged 4 years, who, during her illness, because of a marked enlargement of the spleen, presented a picture of some form of splenic anemia, is reported by Gunn. The girl died. Necropsy revealed atrophic cirrhosis of the liver, cirrhosis of the pancreas and histologic changes in the spleen of the nature of a diffuse fibrosis and fibro-adenitis of the follicles, as described by Banti for Banti's disease. Besides this, a high-grade myeloid metaplasia was found in the spleen and lymph nodes, which is assumed to be of secondary nature. A brother of this child had exhibited the same clinical picture, and had died at about the same age, three years previously.

Associated Carcinoma and Tuberculosis of Uterus.—In a case of associated tuberculosis and carcinoma of the body of the uterus reported by Gais, the latter process was apparently the older one, the tuberculosis developing later as the result of the localization of bacilli from an older distant focus. From the literature, twenty-seven cases in which tuberculosis was associated with carcinoma of the uterus and its adnexa are summarized. Of the total twenty-eight cases now on record, four were tubal carcinomas, eight were carcinomas of the body of the uterus, and sixteen were carcinomas of the cervix.

Folliculoma Ovarii.—A solid tumor of the ovary, 18 by 12 cm., was removed by Manheims from a widow, aged 52, a tripara. Histologic examination showed a large number of roset-like alveoli held together by a stroma composed of spindle cells with relatively long fibrils. In about 30 per cent of the lumina of the rosets, polyhedral shaped isolated cells were found, with clear cytoplasm and deeply staining masses of chromatin, apparently nuclei. Usually these cells were free in the lumina. The tumor belongs to that type described by Gottschalk, and called by him "folliculoma malignum ovarii."

Aspiration of Joints.—The value of aspiration of joints as a therapeutic procedure in septic joints of low virulency is discussed by Lonergan. He says that it will often control the process. The procedure may be repeated, if necessary. Simple measures, such as Bier's hyperemia, poulticing and the use of hot compresses, seem to aid in the convalescence. Such patients may often be saved by arthrotomy, and the possible risk of an open operation avoided if they are aspirated and then carefully watched.

What We Know About Ventilation. A. C. Willard, Urbana, Ill.—p. 159.

Acute Alimentary Disturbances in Children.—A clinical study made by Mitchell of thirty-five children and an analysis of the results of others have convinced him that in infants who had clinical evidence of dehydration the determination of the blood urea nitrogen, uric acid and the carbon dioxide of the blood plasma showed different values, depending on whether or not the infants were suffering from toxic symptoms and hyperpnea. If no toxic symptoms were observed, the blood nonprotein nitrogen constituents were practically normal. If moderate toxic symptoms were present, there usually was a moderate increase of nonprotein constituents, but if the patient showed distinct evidence of toxic symptoms, the blood urea nitrogen and uric acid usually were decidedly increased over normal, although the increase was neither consistent enough nor great enough to indicate that uremia was a primary cause of the fatal termination. A decrease in the carbon dioxide capacity of the blood plasma was found when the dehydrated infants showed clinical evidence of hyperpnea. In other infants in whom hyperpnea was not noticeable, but who were moderately toxic and whose blood usually contained an increase in nonprotein nitrogen constituents, the plasma showed a diminished carbon dioxide capacity in some instances. Usually, however, the carbon dioxide capacity of the plasma was normal when there was no increase in the respiratory rate and depth. The alkali reserve was usually greatly diminished before death. However, since in several infants this did not occur and in several, with equally low alkali reserve, recovery followed, it would seem that the acidosis is an accompanying phenomenon and not a primary cause of either the condition or its fatal termination.

Intra-Abdominal Hernia.—Sudden generalized abdominal pain accompanied by nausea and vomiting, followed by a similar attack four months later was the history of Elston's patient, a girl, aged 16. Abdominal tenderness, with slight rigidity and tympanites, were objective symptoms. At operation there was found a small, evidently congenital, aperture, in the root of the mesentery, hard and ringlike, about as large as a lead pencil. The bowel which had herniated through this aperture was about 76 inches (193 cm.) in length and was gangrenous. The herniated bowel began about 4 inches above the cecal junction and extended toward the jejunum. It was resected and an end to end anastomosis was done by the use of a button which was recovered on the ninth day, and the patient left the hospital in apparent good health.

Blood Transfusion.—Investigation of twenty-five donors who had made more than twenty-five donations each, Powell states, has shown weakness and secondary anemia in only four cases. Five of the donors had given more than fifty, and one had given sixty-three, transfusions. One of the twenty-five who returned recently to be reexamined with regard to the advisability of giving more donations was found to have active pulmonary tuberculosis. One was weak; two had moderate secondary anemia, and the remainder had normal blood and their general health was excellent. This shows that the same donors may be used repeatedly without ill effects to themselves. Because of its simplicity, safety and satisfactory results, the indirect method with sodium citrate is preferred by Powell.

*Jaundice Following Pulmonary Infarction in Patients with Myocardial Insufficiency. I and II. C. S. Keefer and W. H. Resnik, Baltimore. —pp. 375 and 389.

Phenylhydrazine Derivatives in Polycythemia.—The therapeutic effect of phenylhydrazine hydrochloride and acetyl phenylhydrazine was studied by Long in three cases of polycythemia vera, and one case of secondary polycythemia or hypertension. The best results with phenylhydrazine were achieved in the treatment of polycythemia vera. In this condition, with no discomfort to the patient, the blood can be reduced to normal and held there with ease for a considerable period of time. With a normal blood picture, these patients lose the symptoms of their polycythemia and are greatly benefited. In no case could Long detect any signs of liver injury arising from phenylhydrazine.

Experimental Anemia Produced by Phenylhydrazine Derivatives.—An anemia, pursuing a similar course in all the experiments, was produced by Long by the intraperitoneal injection of phenylhydrazine derivatives in rabbits. When the anemia was established, it was possible to demonstrate the presence of methemoglobin in the blood serum. There was a marked increase in the percentage and total number of reticulated red blood cells in the peripheral blood during the period of the anemia, and the hematopoietic system underwent a marked hyperplasia, which progressed until red blood cell production overbalanced red blood cell destruction.

A marked increase in the number of phagocytic cells containing intact red blood cells and pigment was found in the spleen, bone marrow and lymph nodes during the anemia. It was not possible to demonstrate the presence of bilirubin in the blood plasma of the rabbits during the anemic stage. Urobilinogen appeared in the urine on the first day after the injection of phenylhydrazine and remained in demonstrable amounts for about three weeks.

Jaundice in Myocardial Insufficiency.—Keefer and Resnik reported ten cases of myocardial insufficiency in which the sudden appearance of visible jaundice, or the sudden increase in jaundice that was already present seemed directly dependent on the development of pulmonary infarction. The jaundice was due, in all instances, to bilirubinemia. In all these cases, the clinical course was very similar, for death, due to progressive myocardial failure, occurred within a relatively short time.

Bacillus Coli Antiserum.—From young cultures of *B. coli* (from eighteen to twenty-four hour cultures), a soluble toxic substance was obtained by Steinberg and Ecker and an antiserum against this toxic substance was produced. The soluble toxic substance is the principal lethal factor when cultures of *B. coli* are injected into the peritoneal cavity of rabbits. Intravenous administration of the antiserum can avert death in rabbits previously injected intraperitoneally with lethal doses of *B. coli*.

Reversed Passive Anaphylaxis.—Opie and Furth found that anaphylactic shock occurs (in rabbits) when the usual procedure for the production of passive anaphylaxis is reversed; that is, when an animal previously treated with antigen receives the corresponding antiserum by way of the circulating blood.

Effect of Jejunostomy in Experimental Obstruction.—Haden and Orr summarize their findings as follows: Jejunostomy does not prevent the development of the chemical changes of the blood characteristic of obstruction of the jejunum in the dog. Jejunostomy following experimental obstruction of the jejunum has no beneficial effect on the duration of life. There is some evidence that life may be shortened by early jejunostomy. Treatment of jejunal obstruction with physiologic sodium chloride solution tends to prolong the life of animals, regardless of jejunostomy.

Syphilitic Myocarditis in Rabbit.—In the course of routine postmortem examinations of rabbits infected with *Spirochaeta pallida*, six cases of pronounced granulomatous myocarditis were encountered by Brown and Pearce. Spirochetes were not demonstrated in the lesions, but the clinical history and the gross and microscopic appearance of the lesions seemed to warrant a diagnosis of syphilitic myocarditis. The lesions measured 1 cm or more in diameter and histologically were practically identical with those described by Warthin in cases of syphilitic myocarditis in man. These are said to be the first cases of syphilitic myocarditis or of visceral syphilis in the rabbit that have been reported

Experimental Bone Marrow Reactions.—Muller describes the effect produced by the intravenous administration of collargol on the bone marrow of rabbits. Three fairly well defined stages could be recognized: (*a*) an initial stage after comparatively few and small doses, with erythrocytic and endothelial hyperplasia in the bone marrow and with evidences of this stimulation in the peripheral blood in the form of young erythrocytes and normoblasts; (*b*) an intermediary stage which followed the injection of larger amounts of collargol, and which was characterized by a predominant myeloid hyperplasia; (*c*) a final stage with marked bone marrow aplasia and with colloidal silver deposited in endothelial cells as well as in clasmatocytes This was associated with a high grade anemia with low color index, resembling aplastic anemia in its main features. This stage terminated fatally It is suggested that the results may be offered in support of the theory of the endothelial origin of both clasmatocytes and red blood cells.

Nature of Diphtheria Toxin.—The formation of diphtheria toxin is explained by Dernby as follows: The toxin is to its greatest part neither secreted from the living cells, nor is it extracted from the dead bacilli. The bacilli grow, die, and autolyze Simultaneously, proteolytic enzymes of a specific character are liberated These enzymes attack the albumoses and peptones of the autolyzed bacilli as well as of the broth, and some of the primary split products are the toxic substances If the proteolysis proceeds further, the toxin will be disintegrated also.

Intravenous Chemotherapy in Urinary Infections.—Of the various mediums employed by Braasch and Bumpus with intravenous chemotherapy, mercurochrome-220 soluble has been effective in acute and subacute infections of the urinary tract and in occasional cases of acute general sepsis of various types. In chronic infections involving the urinary tract and other tissues, it is not of great therapeutic value. The greatest objection to its intravenous use is its toxicity. Severe reactions are common, marked by prostration, chills and dysentery Two of the 196 patients who received intravenous injections of mercurochrome at the Mayo Clinic during the last year died Necropsy in one case demonstrated that in the absence of any other cause of death toxemia was the probable lethal factor. It is evident, therefore, that mercurochrome should be used intravenously only if emergency demands it. Although the element of danger is ever present, nevertheless, in cases of acute sepsis, when other measures have failed, it merits trial

Therapeutic Value of Mercurochrome, Methenamine and Hexylresorcinol.—Helmholz and Field summarize their results as follows In the dosages used, methenamine is superior to mercurochrome and hexylresorcinol as a urinary antiseptic in cases of infection produced by *Staphylococcus albus* and the colon bacillus *Staphylococcus albus* seems to be very much more vulnerable to the action of methenamine than is the colon bacillus

Ammonium Chloride as Urine Acidifier.—Studies made by Muschat show the value of ammonium chloride as an acidifier of the urine Ammonium chloride in a dosage of 1 Gm (15 grains), three times daily, causes a decided increase in the normal urinary acidity Ammonium chloride in the same dosage may be used to change the reaction in cases of alkaline cystitis

Reduplication of Ureter and Pelvis.—In the case cited by Ormond there was a double pelvis and two ureters, which united in the bladder wall and emptied into the bladder by one orifice.

Intra-Urethral Chancroids.—In Goodman's case, endoscopic examination revealed six small, discrete, tender ulcers, 6 cm from the meatus These ulcers were sharply defined, with a depressed necrotic center, duplicating each other on the contiguous sides of the urethral wall, each measuring about 2 mm. in diameter. These lesions had somewhat the appearance of herpes simplex on the oral mucosa. The remainder of the urethra appeared normal. Cultures were positive for Ducrey's bacillus. Dark field examinations of the urethral lesions were negative for *Spirochaeta pallida* Goodman has found only two cases of intra-urethral chancroid reported during the last forty years.

Bilateral Hydrocele.—In Woodruff's case, the right sac contained 2,220 cc of fluid, and the left sac, 1,800 cc. A plastic operation was done on the skin of the scrotum for shortening

Coleman High Calory Diet in Typhoid.—Sison and Ignacio report on the results accruing from the use of a high calory diet in typhoid. The condition of the mouth was practically not affected by the high calory diet. Nausea and vomiting and diarrhea occurred less frequently. Tympanites was slightly more frequent. Nervous symptoms were present in 9 per cent of the high calory diet cases, but in 31 per cent of the low calory diet cases the duration of the febrile period and the incidence of recrudescence were not affected by the high calory diet. The range of temperature was slightly lower in the high calory cases than in the low calory cases. Relapses were less frequent, and the duration of convalescence was shortened. Complications developed in only 11 per cent of the high calory cases. Mortality in the high calory cases was 2 per cent and in the low calory cases, 18 per cent.

Roentgen Ray Treatment of Aortic Aneurysms. S A. Levey, St Louis.—p 219.

Sella Turcica in Abnormal Children.—Studies were made by Gordon and Bell of the contours of the sella turcica in sixty-four abnormal children The findings were compared with those of 104 normal children. It was found that the shape of the sella does not differ significantly in normal and abnormal children. The type of disorder is not correlated with the shape of the sella There is no formation characteristic of any individual disease The excavation that has been described in mongolian idiots is extrasellar. It may be uncovered or covered by the lesser wings of the sphenoid. It is a normal foundation found with the same frequency in all children and is not characteristic of any known disorder. The size of the sella is not influenced by any of the diseases studied. As in the normal series, there was found no relationship between the size or shape of the sella and the size of the head.

Congenital Dislocation of Hip.—Putti outlines his method of treating dislocation of the hip and reviews the results obtained by surgical and nonsurgical treatment in 700 cases Functional and anatomic success was obtained in 80 per cent for single dislocations and 60 per cent for bilateral. On the basis of 1 879 cases with 2 556 reductions, success has resulted in 90 per cent of the single dislocations, and 65 per cent of the bilateral cases have been improved

Radiotherapy in Malignant Disease of Paranasal Sinuses.—Quick urges early surgical exploration of the paranasal sinuses and biopsy so that earlier diagnosis of new growths may be made With few exceptions, the principles applying to surgical removal of cancer, in general, cannot be carried out in dealing with growths in the paranasal sinuses. Radium and roentgen rays are of value in treating this group of cases, but except in palliative procedures, must be used in conjunction with surgery. Radium and roentgen ray may be depended on to eradicate the tumor tissue if applied accurately and uniformly throughout the growth in sufficient dosage Surgery must be employed to provide exposure for radium application and adequate drainage.

Peritoneum and Abdominal Surgery.—Gutierrez says that the peritoneal sheets of coalescence are remarkably serviceable in abdominal surgery It is through them that certain fixed segments of the digestive tract may be made movable. Intestinal mobilization represents the preliminary and fundamental element in every surgical intervention on an intestinal segment that has become secondarily fixed by the process of coalescence Gutierrez discusses briefly the formation of each of the more important sheets of coalescence.

Vaginal Hernia.—Miles reviews nine cases of vaginal hernia already on record, and reports two additional cases. The cause of these hernias, with one exception, was trauma, following pregnancy or childbearing. A new classification embracing all hernias occurring through the pelvic floor is offered, following the general usage of terminology and classifying it according to its course thus: *Pelvic hernia may be* perineal, pudendal, or vaginal, and vaginal pelvic hernia may be (*a*) anterior or (*b*) posterior Prolapse of the uterus accompanied by a general enlargement of the culdesac and protrusion of abdominal contents into the vaginal vault should be called either elytrocele or vaginal enterocele, and not a hernia The treatment is operative, and the best operation is a perineal one by which the sac is excised and the perineum is repaired, combined with an abdominal operation for obliterating the culdesac.

Thyroid Metastasis to Bones.—In the first of the three cases reported by Simpson, spontaneous fracture of the femur occurred as a result of the presence of a tumor composed of histologically benign thyroid tissue. A small goiter gave no evidence of malignancy. In the second case, the metastasis was to the astragalus. The microscopic picture was that of typical thyroid tissue, and the patient possessed a small, symmetrical goiter which was regarded as clinically benign. The third patient presented signs of vertebral neoplasm with compression myelitis, but with no clinical signs which might direct suspicion to the thyroid gland. Laminectomy exposed a hazel-nut sized tumor in the sixth cervical vertebra, which, on microscopic examination, contained areas of typical thyroid tissue. All these patients later developed unmistakable clinical evidence of malignancy of the thyroid gland, and all died within a year and a half following operation. One case came to necropsy. A review of the literature shows that there is no such entity as the "benign metastasizing goiter"; hence, the use of this confusing term should be abandoned.

Transplantation of Parathyroids in Partial Thyroidectomy.—Since parathyroids will occasionally be removed at operation and identified in the laboratory, Lahey says they should be carefully searched for on the specimen following operation, and, if found, transplanted. The belly of the sternomastoid is the most convenient place into which to transplant them, and care should be taken to see that the cavity into which they are transplanted is dry.

Pylephlebitis and Liver Abscess Following Appendicitis.—Pylephlebitis and liver abscess are not identical. Eliason says they occur as a complication in from 0.1 to 0.4 per cent of the cases of appendicitis. The prognosis is not universally bad, as 54 per cent of the patients recover. Operation through the diaphragm is the treatment of choice.

Hysterotomy.—Oginz believes that the operation of hysterotomy for the interruption of pregnancy and sterilization is of great value in certain cases of pulmonary tuberculosis, cardiac diseases, chronic nephritis and hypertension and in some unusual cases, and could be used to the patient's advantage much more often than has been the practice in this country.

Operation for Prolapsus Uteri.—Johnson reports nearly 90 per cent of cures from his treatment of these cases. He has modified the Watkins operation. The whole anterior surface of the uterus down to the cervix is sewed to the fascia of the anterior vaginal wall. Thus the uterus is firmly fixed in anteversion to the fascia, and the bladder rests on the posterior aspect of the body of the uterus.

Transperitoneal Cesarean Section.—The points emphasized by Polak in his technic are: first, the low abdominal incision; second, placing of the traction suture in the uterus at the upper limit of the abdominal incision which, when held taut, makes a perfect occlusion of the wound; third, separation of the peritoneal flap, including the bladder; fourth, delivery of the fetus by the head; fifth, allowing the placenta to separate spontaneously, and sixth, packing of the uterus with washed iodoform gauze to stimulate its contraction and retraction. This gauze is usually found in the vagina at the end of twenty-four hours. The seventh point is complete occlusion of the uterine wound by the suture of the bladder reflexion over it, which prevents the possibility of peritoneal leakage and intestinal adhesions.

Management of Skin Grafts.—Smith believes that the commonly accepted advice to allow for contraction and to cut the graft one-third to one-half larger than the area to be covered is one of the commonest sources of failure. He insists that the graft must be cut accurately to size and maintained at normal tension. For the same reason, it must be accurately approximated by carefully placed sutures.

Treatment of Acute Postoperative Toxemia of Hyperthyroidism.—In the treatment of these toxemias, Rogers recommends the subcutaneous administration of a boiled aqueous extract of the thyroid—the so-called thyroid residue. It seems to act by stimulation of the terminal filaments of the vagus or parasympathetic portion of the involuntary nervous system and so does not increase the already alarming rapidity of the heart action.

*Function of Right Hemisphere of Brain in Relation to Left in Speech, Music and Calculation. S. E. Henschen.—p. 110.

Hepatolenticular Degeneration.—Corneal pigmentation has been found by Barnes and Hurst in cases described as pseudosclerosis and as Wilson's disease, and in three cases without any observed nervous signs; but in every case in which a postmortem examination of the viscera has been made the presence of cirrhosis of the liver has been demonstrated. It seems clear, therefore, that the corneal pigmentation may be deposited at a stage before the nervous symptoms are so far developed as to give rise to observable clinical signs; further, it apparently never occurs before the liver it diseased.

Prognosis in Disseminated Sclerosis.—Taylor avers that the activity of the poison in disseminated sclerosis is favored by strain or accident. This emphasizes the desirability of complete rest as soon as the condition is recognized, so as to exert a favorable influence on the course of the illness.

Function of Cerebrum.—Henschen reviews facts that he believes to be in favor of the theory of a primary organization of the brain as the original cause of the predominance of the left side of the brain.

*Experiences in Irradiation of Breast Cancer. H. Wintz.—p. 150.
Dysostosis Hypophysaria. A. Schüller.—p. 156.

Roentgenotherapy of Breast Cancer.—Wintz stresses the fact that in order to obtain a cure by the roentgen-ray treatment of cancer of the breast it is essential that the requisite dose for the destruction of the carcinoma cells be applied to the axillary and supraclavicular regions as well as to the tumor itself. Of equal importance with exactly dosed treatment is a carefully planned scheme of after-treatment. For not only are toxins set free by the destruction of cancer cells, but the metabolism of normal cells is considerably changed in consequence of the large area involved. It is now the task of the body to get rid of the decayed cells and to replace the disintegrated tumor by healthy tissue. This difficult task can only be accomplished when the conditions of life outside the hospital are favorable. Special care must be taken when irradiating carcinoma of the breast to prevent lung fibrosis.

Antituberculosis Campaign at Home and Abroad. W. H. Dickinson.—p. 67.
*Pretuberculous Child. A. Massey.—p. 72.
Habitat in Pulmonary Tuberculosis. F. R. Walters.—p. 77.

Use of Roentgen Ray to Estimate Lung Changes in Tuberculosis.—Lynham asserts that when it is established that a patient is suffering from pulmonary tuberculosis, although, as a rule, it is on the general clinical condition that the progress of the case must be judged, roentgenograms taken at intervals provide valuable help in estimating the changes in the lungs.

Pretuberculous Child.—A new definition of the pretuberculous child is suggested by Massey, that is, one who, by reason of tuberculous family history and contact, of past debilitating disease, or of present physical condition, is unusually likely to become the victim of active tuberculous disease; in addition the term is extended to include those children in whom the presence of tuberculosis is already suspected, but whose condition will not admit of precise diagnosis.

Paragonimus Cyst of Abdominal Wall.—Ova of *Paragonimus westermanii* were present in the sputum and in the feces in the case cited by Choy and Ludlow. In July, 1924, following an attack of fever marked by loss of appetite and constipation, the patient suffered severe pain in the epigastrium, accompanied by a swelling in the same region. After catharsis, the pain subsided but the tumor persisted and increased in size slowly until, on admission to the hospital, it was 6 cm. in diameter. The growth was slightly bluish and fairly soft. It was very vascular and adherent to both skin and the muscle fascia. In the vascular connective tissue stroma were found the ova of *Paragonimus westermanii.*

*Oxycephaly. D. M. Greig.—p. 189.
*Postmortem Tuberculous Lesions in Four Hundred and Four Consecutive Examinations. T. R. R. Todd.—p. 219.

Oxycephaly.—Greig illustrates by original cases the clinical features of oxycephaly, describes in detail the skull of an adult oxycephalic patient, and distinguishes true oxycephaly from certain somewhat similar cranial deformities with which it has been confused. Incidentally, he pleads for restriction of the term "oxycephaly" to a specific cranial deformation.

Postmortem Tuberculous Lesions.—Of the total 404 cases in which Todd performed a postmortem examination, 284, or 70 per cent, showed definite signs of tuberculosis. The remaining 120 included forty-six with patches of fibrous tissue or scars in the lungs and pleurae, twelve with only pleural adhesions, and sixty-two with no signs anywhere of tuberculosis. The greatest number of cases of tuberculosis occurred in the age period of from 51 to 60; namely, eighty-one cases, or 32 per cent. There were twenty-two cases of active tuberculosis. In four of these, death was caused by other diseases. In three of the cases the focus was in the lungs, and in the fourth it was in the mesenteric glands. Calcareous lesions were found in 193 cases, caseous lesions in sixty-six cases, and healed lesions in three cases. In the latter, there were no signs of calcification or caseation. The lungs were involved in 171 cases; the lungs only in eighty-one cases. In fifty-two of these eighty-one cases the lesions were calcareous; they were caseous in twenty-four, active in four, and healed in one. Three of the four active cases were fatal. Of the caseous cases, nine were active and fifteen were latent or inactive; that is, completely encapsulated. Glands were involved in 201 cases, the bronchial lymph glands being affected in sixty. Among these adult patients, none died of tuberculosis. The lungs and bronchial glands were simultaneously affected in the same patient fifty-nine times. Two of these were fatal. The combination of lungs, bronchial and mesenteric glands occurred five times, and that of cervical, bronchial and mesenteric glands thrice. The bronchial glands were infected altogether in 144 cases, less fifteen fatal cases. The majority of the lesions in glands were calcareous, and the remainder were caseous, completely or partially encapsulated. The mesenteric lymph glands were affected in sixty-four cases, only twenty-two of these cases being in combination. The mesenteric glands are at the high level of 66 per cent during the first decennium, and then drop steadily to about 8 per cent in the fifth decennium, about which level they remain till the end. In this series of sixty-four cases, forty-six were calcareous, seventeen were caseous, and one was in the early active stage of infiltration. The size of the nodules varied, and also the number present in each case was not constant. All glands had some sort of connective tissue envelop enclosing them in the mesentery.

Case of Myxedema Associated with Exophthalmic Goiter. R. M. Kar.—p. 181.
Case of Pseudohypertrophy. H. Prasad.—p. 182.

Treatment of Myeloma.—Hance contends that the treatment of myeloma by curettage and autogenous bone grafting is worthy of a more extended trial, and, provided rigid asepsis is observed, holds out the promise of good results. Cancellous grafts, as malleable bone forming mediums, tend, in association with graduated movements and accurate splinting, to an earlier restoration of function and symmetry than do grafts of compact bone.

Action of Organic Antimony Derivatives.—The action of a number of organic antimony derivatives has been tested by Chopra on cats. All these substances have a more or less depressing effect on the heart, circulation and respiration. The systemic blood pressure falls, while the pulmonary blood pressure rises. The volume of the spleen is markedly increased, while the volume of the intestine, kidney and limbs decreases.

Eradication of Jigger Scourge.—Being unable to control infection with jigger fleas in any other way, Jolly resorted to having the troops go barefoot with daily foot inspection and the removal of jiggers. In a month's time the jigger scourge had practically ceased to give trouble. The success of this experiment depended on the fact that the jigger flea can only breed in the body of its host, and that daily inspection prevented this by detection and removal of the female jigger before it had time to develop its eggs. The victims of the parasites themselves became the trap that lured the jigger to its destruction.

Emetine Treatment of Amebiasis.—In seventy cases of amebiasis, including six relapses, the patients were treated by Deuskar with emetine administered intravenously with a case mortality of about 12.5 per cent. Altogether over 1,000 injections were given. Nine injections, each of 1 grain (0.06 Gm.), were given on nine consecutive days, followed by an interval usually of six days, after which another six injections were similarly given, so that each patient at the end of the course received a total of 15 grains (1 Gm) of emetine The use of emetine intravenously, besides being painless, was found safe and simple and appears to be practically free from the dangers it is commonly supposed to involve

Experimental Dietary Bile Duct Calculus Formation —Fujimaki states that animals kept on the protein and vitamin A deficiency diet formed concretions in a relatively short period a shorter time than the animals fed on either vitamin A deficiency or vitamin A and C deficiency diet Animals fed on the protein deficiency diet died and did not form calculi Animals fed on the vitamin A and inorganic phosphorus and calcium deficiency diet formed calculi in a very short time In these cases bile duct stones were found taking the longest period of all Urinary calculi found among the animals fed on the vitamin A and inorganic phosphorus and calcium were carbonate calculi (while the stones of the animals fed on the vitamin A and vitamin A and C deficiency diet were phosphatic calculi) Bile duct calculi consisted of abundant calcium salts besides cholesterol and pigment

Coccoid Formation of Diphtheria Bacillus —During the repeated culture of *B diphtheriae* on Loffler's blood serum medium Yarisawa noticed that organisms of some strains assume coccoid forms Such alteration takes place sometimes even in Loffler's blood serum medium The most typical coccoid alteration takes place in blood agar culture transplanted from blood serum medium A similar phenomenon may be seen on glycerine agar or ordinary agar medium These strains are capable of producing toxin When a suspension of the coccoid organisms is injected into guinea-pigs, certain toxicity is manifested Such strains are not particularly rare Fourteen per cent of Yarisawa's collection of *B diphtheriae* strains manifested the coccoid alteration on certain mediums

Three Cases of Suppuration in Mastoid Cells with Intact Tympanic Membrane H B Tawse —p 231
Scarlet Fever with Otitis Media H R Souper —p 233

Function of Aural Cerumen —The data given by Creed and Negus point to the lack of any definite association between accumulations of cerumen and middle ear disease, and the absence of any typical distribution would indicate that it has no important function in man, and that an increase or diminution in its amount, or changes in its consistency, cannot be taken as an indication of the condition of the middle ear In otosclerosis, however, it has frequently been observed that there is marked deficiency of secretion of cerumen It is evident from the results of the examinations made that aural cerumen is most decidedly not bactericidal, but that, on the contrary, it serves as a medium in which organisms of great variety may multiply; this is proved by the fact that bacteria were found to be more numerous in specimens of cerumen that had been collecting in the meatus for a considerable time than in those of recent origin Therefore, it would appear that the only useful function cerumen can serve is to prevent mechanically the entrance of dust and insects to the deep meatus

*Ankylostomiasis Comparative Efficiency of Carbon Tetrachloride, Chenopodium and Thymol in Treatment C Manalang —p 101
*Subacute Inguinal Poradenitis or Climatic Bubo E P de Bellard —p 113

Treatment of Ankylostomiasis —Manalang's report deals with the results obtained from carbon tetrachloride, chenopodium and thymol used against hookworm All the way through carbon tetrachloride was superior to the other drugs Carbon tetrachloride in doses of 1 cc per 5 5 Kg, 7 Kg and 10 Kg of body weight, and mixed with magnesium sulphate cured 55, 52 34 and 53 per cent, respectively; chenopodium 40 per cent, thymol, 26 3 per cent, with the first treatments, and 73 75 61, 67, 33 and 20 per cent, respectively, with the second treatments The only objection to carbon tetrachloride noticed was that it produced dizziness, vomiting and a varying degree of debilitation These symptoms, however, are practically nil when the drug is given in doses of 1 cc to 10 Kg body weight and in combination with magnesium sulphate The carbon tetrachloride must be repurified to be safe Ill effects were not noted with either chenopodium or with thymol

Subacute Inguinal Poradenitis —Subacute inguinal poradenitis is described by de Bellard as an autonomous pathologic entity of unknown causation distinct from all the other usual forms of adenitis but very closely resembling pathologically a tuberculous adenopathy In the tropics, the disease attacks almost exclusively young men of the white race recently arrived from colder climates It is endemic in certain zones, with occasional mildly epidemic exacerbations These outbreaks seem to coincide with long periods of drought and extreme heat A long prepuce and uncleanliness of the genitals strongly predispose to it The disease is manifested by an adenitis of the inguinocrural glands, characterized by multiple intraganglionar purulent foci accompanied by periadenitic inflammatory lesions, of a hemorrhagic and suppurative type, with the formation of dense and extensive periglandular adhesions All nonsurgical treatments so far tried have failed to produce uniformly satisfactory results, besides entailing serious loss of time Poradenectomy, or the radical excision of all diseased glands, should be the treatment of election and constitutes the only procedure that promises a quick recovery

*Use of Hydrochloric Acid and Sodium Bicarbonate in Treatment of Certain Common Dyspepsias. F. L. Apperly.—p. 354.

Hydrochloric Acid and Sodium Bicarbonate in Dyspepsias.—Apperly says that before the intestine will accept chyme from the stomach, it must be of a certain salt strength or osmotic value. Any value above or below this causes rejection by the intestine of the food back into the stomach, where it remains until such time as it has by the addition of secreted hydrochloric acid or of sodium chloride or by dilution obtained the correct salt strength. The stomach then empties. The value to which chyme must attain is a constant for each individual, but varies in different individuals from 80 degrees to 130 degrees; that is, about isotonic with sodium chloride in blood (100 degrees equals one-tenth molar solution). When the strength of sodium chloride or acid in the various secretions is low, there is difficulty and delay in the attainment of the required salt value of the food. This results in increased and prolonged regurgitation of duodenal fluids, with, in consequence, lowered acidity and prolonged evacuation time. The administration of hydrochloric acid, sodium bicarbonate or sodium chloride has the effect of raising the salt strength of the food more rapidly to its required value, with the result that regurgitation of duodenal fluids is diminished, acidity is raised and the stomach empties more rapidly. The accommodation of the volume of gastric contents to gastric tonus is thus more rapidly made with relief of symptoms.

*Hematuria in New-Born Child. N. Dale.—p. 385.

Hematuria in New-Born Child.—Dale reports a case of hematuria, occurring in a child, aged 3 days. During the duration of the hematuria (three days) the infant manifested no signs or symptoms of renal colic and was in good condition throughout. One other interesting feature was the presence of small subungual hemorrhages on four of the fingers of the left hand. The family history was apparently clear. A Wassermann test of the mother's blood was negative.

*Etiology of Mumps. Y. Kermorgant.—p. 301.
Recklinghausen's Bone Disease. G. Guillain et al.—p. 313.

Etiology of Mumps.—Kermorgant experimented with the sediment from centrifugation of the weak salt solution used for mouth rinsing, at the onset of mumps. A dose of 0.1 cc. was injected into the parotid gland or duct of monkeys. From seven to twelve days later the animals developed bilateral parotitis; one presented multiple localizations of an infectious process resembling mumps. The centrifuged sediment cultivated in diluted horse serum revealed the presence of a special spirochete, associated with a bacterium. While separate cultures of this bacterium could be easily obtained, it was impossible to isolate the spirochete. Three monkeys were injected in the parotid or testicle with cultures of the associated bacterium and spirochete. One developed bilateral parotitis; another mumps with bilateral orchitis; the third a bilateral orchitis. The inoculations were also positive in rabbits. Cultures of the isolated bacterium injected alone gave negative results. When whole cultures were passed through a filter, thus withholding the bacteria, there was no growth of the spirochete in the filtrate, until a trace of the bacteria culture was added. Serums from subjects with a history of mumps displayed a lytic and agglutinating action on the spirochete. There was no agglutination of the associated bacteria. The spirochete presents a shiny cylindric body, spirally coiled, with a flagellum at the end. Reproduction is by division. Separated granules on a flagellum are found in the filtrate, where they may give origin to the typical spirochetes. On neo-arsphenamine treatment of the experimental mumps, the orchitis subsided immediately.

*Ultraviolet Rays and Growth. M. Springer and A. Tardieu.—p. 394.

Action of Ultraviolet Rays on Growth.—Springer and Tardieu conducted their experiments on young rabbits which were born and kept further in a dark cellar. While the two strongest and best developed served for controls, the three weaker were treated with ultraviolet rays. Three exposures a week, to a total of fourteen, were given with gradually increasing doses. The skin of the exposed rabbits had not been shaved. The five animals were equally and properly fed. All the treated rabbits grew normally and gained in weight. On the contrary, the weight of the controls became gradually reduced; they finally developed paralysis and died. There were no signs of rickets. They theorize that the formation of ozone, enhanced production of electricity in the organism, as well as the rise of osmotic pressure, explain the favorable action from ultraviolet rays. These rays seem to stimulate the trophic centers and the functioning of the endocrine glands and, consequently, nutrition and growth.

95: 399-424 (April 27) 1926

*Perforation of the Aorta. M. Couto.—p. 406.
*Serodiagnosis of Cancer. H. Hartmann.—p. 412.
Filtrable Virus and Heredity in Tuberculosis. F. Arloing and A. Dufourt.—p. 416.
*Rôle of Water in Acid-Base Balance. S. Ramos.—p. 420.

Syndrome of Perforation of the Aorta.—Couto reports three cases of perforation of the aorta, communicating with the pulmonary artery, which were clinically diagnosed. The symptoms suggesting the diagnosis were the instantaneous appearance of dyspnea, distress, cyanosis and pain in the chest, with a systolic murmur and aortic thrill. This combination presents the pathognomonic picture of perforation of the aorta. Localization of the murmur and thrill to the left of the sternum points to a communication with the pulmonary artery, or exceptionally with the right auricle or ventricle. Localization on the right of the sternum indicates communication with the innominate vein or superior cava.

Serodiagnosis of Cancer —Hartmann describes an improved technic for the Botelho seroreaction in malignant disease The protein content of the serum has to be brought to a standard figure, 7 or 8 per cent, diluting or concentrating it Then 0 5 cc of the serum is mixed with 3 cc of a 1 per cent solution of nitric acid in 0 75 per cent sodium chloride solution On the light foam which forms on agitation, he drips 0 5 cc of a solution of 1 Gm of iodine and 2 Gm of potassium iodide in 210 Gm of water The test is negative if the content remains clear, positive, if it becomes turbid In 145 patients with cancer the reaction was positive in 90 4 per cent, in fifty-five patients with other diseases it was negative in 85 5 per cent The reaction was positive in women in the first months of pregnancy In seventeen subjects operated on for cancer the reaction remained positive in twelve, and the cancer recurred in all in this group In five, the test became negative after the intervention, and recurrence was observed in only one The reaction became negative in six of twenty-one cancer patients after roentgen-ray or radium therapy, all appeared clinically cured In fifteen, the reaction continued positive, and all except one developed recurrences The reaction was positive in all the rabbits with tar cancer and it was negative in normal animals except in one gravid rabbit

The Importance of Water for the Acid-Base Balance of the Blood —Solano Ramos warns that loss of water in purging, vomiting and hemorrhage is responsible for many disturbances ascribed to other causes at operations The law of Arrhenius explains the acidosis in these conditions as the result of dehydration

Bulletins de la Société Médicale des Hôpitaux, Paris

Masked Forms of Amebiasis Trabaud —p 614

Urine Phenols in Infants —Debre Goiffon and Crama noted an increase of the urine phenols from an average of 0 008 to 0 024 per cent in infants with digestive disturbances The phenol content returned to normal with recovery, or rose still higher when the condition grew worse Increase of phenols occurred also in acute infectious diseases, as bronchopneumonia, otitis, or with suppurations, as pyodermitis, without coexistence of digestive disturbances The phenols eliminated by the urine seem to be a better index of the intensity of intestinal putrefaction than the elimination of indol or skatol

Mediastinal Hernia Complicating Artificial Pneumothorax —In Bernard, Valtis and Farret's three cases, the mediastinal hernia was caused by insufflation of excessive amounts The weak points of the mediastinum yielded under the high gas pressure in the pleural cavity The hernia occurred from two to six months or three years after the beginning of the pneumothorax treatment The ages ranged from 17 to 25 In these three cases, the hernia was in the left pleura, and projected on the right side The hernia subsided with longer intervals and less pressure The hernia did not impede the favorable course of the artificial pneumothorax

Hyperglycemia Without Glycosuria —Rathery and Froment found an excess of blood sugar, without glycosuria, in subjects with skin and joint affections, and with disease of the kidney, liver or biliary tract They observed this also in four cases of obesity, in one of postencephalitic parkinsonism, the adiposogenital syndrome, and cancer of the vertebrae The hyperglycemia without glycosuria does not seem to be connected with functional disturbances of the kidney as in nephritis It is apparently entailed by some disturbance in carbohydrate metabolism, pointing to a prediabetic condition

Prolonged Use of Epinephrine in Asthma —A remarkable tolerance for epinephrine was manifest in Pagniez and Escalier's tabetic patient with asthma The paroxysms, as frequent as four a day, could not be relieved otherwise than with injections of epinephrine The woman had been given 2 172 injections, of 0 0005 Gm each, within eighteen months The total of epinephrine injected in 1924 amounted to 0 696 Gm The injections appeared to be without influence on the blood pressure, but were probably responsible for other phenomena such as paleness, accelerated pulse and palpitations Finally a few grave syncopes occurred, and the injections were discontinued Evidently not the blood pressure alone, but other signs may serve as the criterion of the tolerance for epinephrine

Sympathectomy for Arteritis Obliterans —Cain and Hamburger report a case of periarterial sympathectomy on the brachial artery to relieve arteritis obliterans in the right hand The usual remedies as well as antisyphilitic treatment had been without avail The intolerable pain subsided completely two days after the operation, the aspect of the hand changing gradually to normal Three weeks later the woman was able to begin to use the hand They add that the interval since the operation is only one month

Alimentary Anaphylaxis and Acid-Base Balance.—Parisot, Simonin and Verain observed a case of intolerance for milk, eggs and peas in a woman, aged 30 Ingestion of a minimal portion of any of these substances induced, among other phenomena, urticaria, nausea, diarrhea, headache and fever (the woman was tuberculous) Examination of the acid-base balance revealed a low *pн* and reduced alkali reserve A mixture of equal parts of sodium bicarbonate and citrate was given by mouth in a daily dose of from 15 to 30 Gm, in water The alkali reserve rose from 42 to 63 per cent (by volume) in ten days Then every day one of the previously nontolerated substances was given, and no anaphylactic manifestations were noted Since then the woman eats freely of the long forbidden foods

Rheumatism in Etiology of Mitral Stenosis —Merklen and Schneider draw their conclusions from thirty-two cases of rheumatic mitral stenosis The disease occurs chiefly in women and is frequently associated with dystrophic conditions This suggests that the female endocrine glands present a favorable ground for the development of stenosis, especially if there is any disturbance The rheumatic virus seems to affect first the thyroid, which seems to be more vulnerable in women than in men Consecutively other glands are involved, thus inducing humoral and dystrophic changes responsible for the mitral stenosis

Death from Fixation Abscess —Comby cites a case in which death was apparently caused by a fixation abscess This occurred in South America, where the fixation abscess was applied for treatment of dementia praecox, in a boy, aged 14 It is possible that too large a dose of turpentine (2 cc instead of the usual 1 cc) may be incriminated for the tissue necrosis and consecutive fatal hematoma

Cheyne-Stokes Respiration in a Decerebrate Dog.—Pachon and Delmas-Marsalet divided the crura cerebri in a chloralosed dog. The corpora quadrigemina were left intact. The animal was then placed in a thermostat; it developed Cheyne-Stokes respiration analogous to that in man, for over two hours. Obviously the posterior corpora quadrigemina do not share in the occurrence of Cheyne-Stokes respiration; it is essentially a phenomenon from insufficiency of the brain.

Rôle of Calcium Salts in Transmissible Microbic Autolysis.—To test tubes containing 5 cc. of an alkalized bouillon, was added one drop of a 1 per cent solution of calcium chloride or fifteen drops of 1 per cent sodium oxalate. Bordet used for the experiments dysentery bacillus bacteriophage element (A) or a bacteriophage obtained from the action of a lysogenic colon bacillus on the dysentery bacillus element (L). Two drops of one element were introduced in each of the calcium or oxalate tubes. The tubes with the A element were inoculated with colon or dysentery bacilli. Lysis was manifest in the tubes with oxalate or calcium, in the presence of the A element, while with the L element, microbic lysis occurred only in the tubes with calcium. The L element in the oxalated bouillon seemed to be deprived not only of the lytic property but also of the power of regeneration. On the other hand, the regeneration of the A element occurred in both the oxalate and the calcium bouillon. The regenerating power was still retained after numerous passages in oxalate bouillon inoculated with the sensitive microbe. Regeneration of the L element and its lytic action in calcium bouillon did not seem to be impaired by previous contact with sodium oxalate.

Fixation of Uterus by Ligamentopexy. Cotte and Peycelon.—p. 241.
*Adenoma of Uterine Cervix. E. Douay and A. Soïmaru.—p. 245.
Malformations of Lower Part of Body. M. S. Serdukoff.—p. 264.
Pituitary Extract. E. A. R. de Cotret.—p. 276.

Adenoma of Uterine Cervix.—Douay and Soïmaru have treated forty cases of adenoma of the cervix within three years. The affection was most frequent between the ages of 30 and 50; one patient was 72 years old. The adenoma may be localized, and present a vegetating, polypous or cystic form. A diffuse adenoma, occupying the whole of the cervix was noted in 78 per cent of the cases. Under the influence of caustics or the galvanocautery, the adenoma may develop into epithelioma, especially the vegetating form, unless the destruction has been complete. Amputation of the cervix apparently induces a definite cure.

27: 241-384 (March) 1926

*Tuberculosis of the Knee. P. Fredet.—p. 241.
Strictures of Inflammatory Origin in the Rectum. Radice.—p. 260.

Technic for Resection of Tuberculous Knee.—Fredet gives an illustrated description of his method for extracapsular resection as applied in twenty-seven patients, aged from 17 to 61. All, except two, seemed clinically cured; there was consolidation of the bones in three months, with restoration of function. Roentgenograms showed perfect union of the bones. Some of those thus treated were able to resume hard manual work. There was no operative mortality.

Marseille Médical

63: 545-600 (April 5) 1926. Partial Index

Radium and Surgery in Cancer of the Uterus. G. Bonnal.—p. 545.
*Case of Fibrinuria. E. Chauvin.—p. 561.
Dementia Praecox and Mental Confusion with Pulmonary Tuberculosis Wahl.—p. 566.
Meningeal Hemorrhage with Anthrax Septicemia. Rouslacroix and F. Trabuc.—p. 574.
Malignant Edema Contracted at Necropsy. F. Trabuc.—p. 581.

Fibrinuria with Cancer of the Kidney.—The urine of Chauvin's patient coagulated to such an extent that it clung to the receptacle when it was turned upside down. The phenomenon occurred repeatedly, without association of any characteristic symptoms. Examination confirmed the fibrinous nature of the urine clots. At the operation, the kidney cancer was found partly covered by successive layers of clotted urine. Fibrinuria is usually considered a symptom of bladder origin, but in this case the kidney was responsible for it.

59: 385-404 (April 24) 1926

Inaugural Lecture of Pathology Course. Rathery.—p. 385.
*Strophulus. P. Vallery-Radot and P. Blamoutier.—p. 398.
Oxygen Treatment of Whooping Cough. G. Boeldieu.—p. 401.

Peptone Treatment of Strophulus.—Pasteur Vallery-Radot and Blamoutier used peptone desensitization treatment with excellent results in twenty children, aged from 1 to 4, with this papular eruption. The action was immediate in sixteen, retarded in four. The most rapid and durable effect was apparently induced with a preparation of meat and fish peptones mixed with egg and milk extracts. A teaspoonful was given an hour before each meal. Children under 3 years were fed four times a day, the older only three times. A suitable diet was strictly observed, avoiding substances liable to induce the rash, especially eggs. The peptone was given for ten days, the series repeated at five day intervals or longer, until a month after the last papule had disappeared. The treatment was continued for months to prevent fresh outbreaks of the rash. The children were reexamined from a month to a year later; no instance of recurrence was found.

34: 465-480 (April 14) 1926

*Nitrous Oxide Anesthesia. E. Desmarest.—p. 465.
Mineral Water Treatment of Asthma. J. Galup.—p. 466.
Fluorosis or Fluorin Cachexia. H. Cristiani.—p. 469.
Oxalic Acid in Cerebrospinal Fluid. M. Nathan.—p. 471.

Nitrous Oxide Anesthesia.—In Desmarest's opinion, nitrous oxide is especially advised in exhausted, infected or anemic patients, when chloroform or ether is contraindicated. Owing to the hypertension-inducing effect nitrous oxide maintains the heart action and is, therefore, useful in prolonged operations. It was never followed by postoperative acidosis in his diabetic patients. It is the best anesthetic for minor operations, in reduction of dislocations, and painful dressings. It seems to be more effectual and less dangerous than ethyl chloride. No complications on the part of the lung, liver or kidney were ever observed.

34: 481-496 (April 17) 1926

*Sanocrysin Treatment. L. Bernard.—p. 481.
Anatoxin Immunization Against Tetanus. Zoeller and Ramon.—p. 485.
Homo-Organic Hormones in Man. C. Richet, Jr.—p. 486.
Marvels of the Bird Wing. Chapeaux and Servajean.—p. 491.

Sanocrysin in Pulmonary Tuberculosis.—Bernard treated twenty-six tuberculous patients with sanocrysin for a few months. The gold salt solution was injected intravenously (0.25 Gm. to 1 Gm.). A total of 10 or 12 Gm. was never surpassed. Favorable results, obviously due to the treatment, were noted in six men and three women; favorable results in which, besides the sanocrysin, other factors might have been responsible, were noted in eight men. The action was null in four men and three women, and unfavorable in two men, causing death in one. The treatment appeared most effectual in the ulcerative form of tuberculosis, with cheesy degeneration and an acute course. The effect was insignificant in the chronic form. The conclusion is that sanocrysin *does not seem to have a specific action on pulmonary* tuberculosis.

*Pylorostenosis in Infants J Estella y B de Castro —p 129
*Habitual Vomiting of Infants R Garelly —p 145
*Pathogenesis of Pylorospasm Damaso Rodrigo —p 165
Multiple Malformations in New Born Infant of Syphilitic Father F Carajas —p 172

Dietetic Treatment of Pylorostenosis in Infants—Estella concludes from his extensive study of pylorostenosis in infants that there are no certain signs for differentiation of the organic and functional forms, and consequently, medical measures should be given a thorough trial first The indication for operation depends on the symptoms, clinical course, radiologic, digestive and trophic findings without being misled by published statistics Thick cereal owes its efficacy not only to its consistence but to the abundance of carbohydrates and the lack of fats

Habitual Vomiting in Infants—Garelly states that 25 1 per cent of 442 infants examined vomited more or less regularly after nursing, from some unknown cause If the peristolic functioning seems excessive, while the milk coagulates abnormally slowly, treatment should aim to promote coagulation, there is less tendency to vomit when the stomach contents are of a thick consistency Condensed milk might be given a trial, and alkalis with excessive acidity Sodium citrate has the advantage that it retards coagulation of the milk and allows better penetration by the digestive juices while neutralizing the irritating acid Danielopolu has demonstrated that drugs which act on the involuntary nervous system affect the vagus or the sympathetic according as the dose is large or small Holding the child erect promotes expulsion of gases As most of these children are gaining in weight, and as the vomiting often ceases spontaneously, it must be regarded as merely an exaggeration of a physiologic process

Pathogenesis of Pylorospasm—Damaso Rodrigo comments on the variability of the causes which may induce pylorospasm In a case of habitual vomiting described, spasmophilia and vagotony could be excluded and the symptoms subsided at once when a teaspoonful of a 10 per cent solution of bismuth carbonate in an acacia solution was given immediately before and after feeding This treatment was suggested by the observation that the infant, who had been vomiting regularly almost from birth, did not vomit the contrast barium suspension, given for roentgenoscopy.

*Myoclonia E Portu Pereyra and J M Estape —p 1
*Cephaloplegia A Carrau —p 11
A Case of Dermatomyositis J Bonaba —p 15
Protection for Mothers and for Children G Araoz Alfaro —p 21.
*Case of Essential Meningeal Hemorrhage J A Bauza —p 38
*Meningitis of Obscure Etiology Alice Armand Ugon —p 43
Congenital Myatonia A Carrau and Penco —p 51

Myoclonia—In two of the four cases described, the myoclonus was probably due to epidemic encephalitis as there were hundreds of cases of epidemic hiccup in town at the time and many cases of epidemic encephalitis developed afterward In both these children the clonic spasms subsided during sleep, and the cure was complete in eighteen or fifty-six days, under psychotherapy The clonic spasms became more pronounced when the child was excited In another case the myoclonia was traceable to birth injury, which had entailed paresis of the right arm and torticollis, in the fourth, to a convulsion at the age of 2 after which the myoclonus had developed and progressed The clonic spasms occurred in paroxysms, especially severe after excitement The cerebrospinal fluid was normal in these two chronic cases Myoclonia seems to be a striatal affection (hemorrhage, softening) for which various morbid causes may be responsible

Cephaloplegic Form of Anterior Poliomyelitis.—Carrau recalls that diphtheria as well as infantile paralysis may be responsible for the sudden cephaloplegia, with loss of tendon reflexes and spontaneous recovery in five to twelve days, to which Figueira called attention first He was unable to demonstrate conclusively the connection with acute poliomyelitis as the children showed no other symptoms Carrau here provides the missing link, as the child presented the typical cephaloplegia [illegible] ccompanied by symptoms of unmistakable poliom[illegible] which ran a long course with a final trend to rec[illegible]

[illegible] Hemorrhage of Unknown Cause.—Bauzá's [illegible] was a girl approaching puberty who suddenly [illegible]ped symptoms of spontaneous subarachnoid hemorrhage [illegible] favorable course without sequelae, suggests that it was of essential nature, possibly an attempt at vicarious menstruation as a drop of blood was found on the body linen the tenth day.

Meningitis—In two of the three cases described the symptoms indicated epidemic meningitis but no meningococci could be detected The children aged 3 and 5, recovered under serotherapy In the third case the clinical picture was that of tuberculous meningitis, but the child recovered in six weeks and inoculation of animals was negative The bacteriologic findings in all three had been constantly negative

The Oculocardiac Reflex in Surgery.—Valerio urges testing the sympathetic nervous system before general anesthesia, as a routine practice With a positive oculocardiac reflex, chloroform should be avoided, he says and ether should be preceded by atropine With exaggeration of the reflex, inhalation anesthesia should not be attempted With inverted oculocardiac reflex, the prognosis is relatively favorable, but if the reflex is abolished, the prognosis is grave

1 95 110 (Feb 20) 1926

*Treatment of Epitheliomas of the Skin Cassio de Rezende —p 95
*Thrombosis of the Heart M Torres —p 100 C cn

Caustic Treatment of Epitheliomas of the Skin.—De Rezende's arsenic paste has proved its efficacy *in nearly ten* years' experience It does not compete with radiotherapy, but when the latter is not available, the intense inflammatory reaction to the daily application of the paste destroys the lesions down into the subcutaneous tissue. The photographs reproduced confirm the complete cure, one in a man of 80. The vehicle is resin cerate, 10 Gm., to which are added 0.25 Gm. each of arsenious acid and copper sulphate; 0.5 Gm. of antimony and potassium tartrate and 0.75 Gm. of quinine, with 1 Gm. each of antipyrine, phenol crystals, camphor, chloral and menthol. He ascribes the rapid healing of the lesion after suspension of the applications to the intense edematous reaction in the tissues around. In the cases mentioned, three applications completed the course in three weeks or a month.

Thrombosis of the Heart.—Torres concludes his long study of endocarditis with vegetations in the heart wall. He says that it is comparatively common in Rio in patients with grave cardiac insufficiency. Seven cases are described with necropsy examination. The valves were free from recent inflammatory changes. The thrombi adhere to the parietal endocardium, and there is always infarction of the lungs, kidneys, brain and spleen. There is usually no history of acute articular rheumatism. He proposes the term endocarditis muralis for this afebrile variety of endocarditis.

Gonococcal Ophthalmia. Espildora Luque.—p. 60.

Nephropexy.—Bisquertt suspended the floating right kidney in the case described with a strip of fascia lata. The strip was 1½ cm. wide and was passed under a bridge cut for it in the front and rear of the capsule at the superior pole; with this the kidney was suspended from the lowest rib. He has been applying this technic for several years and always with gratifying results.

Gonococcus Spondylitis.—Coutts attributed the vertebral disturbances to the gonococcus by exclusion, the man having contracted gonorrhea within the year. An intense focal reaction followed an intradermal injection of a gonococcus vaccine (700 millions of living gonococci and three days later, 2,000 millions). The man was able to get up in two days after the last, and conditions rapidly returned to clinically normal.

Hemotherapy in Mumps.—Coutts and Vicuña report that autohemotherapy had a prompt and decided influence on the orchitis and other genito-urinary complications of mumps in a recent epidemic. One of the five young men whose cases are described had extreme congestion of the prostate in addition to orchitis and epididymitis, and retention of urine compelled catheterization. They injected 5 cc. of own blood four or five days in succession. The fever dropped at once after the first injection.

Teluric Vibrations and Segmentation. A. Mary.—p. 41.

Erythema Nodosum.—Aráoz Alfaro asserts that erythema nodosum may be the manifestation of various infections, but tuberculosis can be incriminated in the majority. In certain cases it seems to be a primary affection representing an attenuated and masked form of tuberculosis. He has encountered another group of cases in which the erythema nodosum seemed to be the final episode in a fever continuing through several weeks in children with glandular disease and positive tuberculin test. In these cases, the erythema seemed to act like a fixation abscess, arresting the bacillary fever and materially improving the general health. One infant, 18 months old, had been having fever for two weeks and miliary tuberculosis was feared, but the discovery of a nodule on the leg suggested the possible onset of erythema nodosum, and he notified the parents that there would probably be a crop of them, with high fever, after which the child would be healthier than before. The course of the case realized his prophecy completely. In a second case of the kind the child was 2 years old, and both have been in much better health since the erythema a year and a half or two years ago.

Diagnosis of Stomach Disease.—Escudero has found the gastric contents apparently normal in certain cases of functional or organic derangement of the stomach. In 401 stomach patients examined, hypoacidity was found in 54.4 per cent of the 248 cases of functional dyspepsia and in 52.2 per cent of the 153 with organic disease; normal acidity was found in 29 and 24.1 per cent respectively, and hyperacidity in 16.5 and 23.5 per cent. Repeating the analysis gave conflicting findings in 30 per cent. There does not seem to be any definite expression of the stomach chemistry corresponding to any special type of gastropathy.

Malaria Treatment in General Paralysis.—Bosch and Mó report results surpassing anything previously realized. Of their forty patients thus treated, 17.64 per cent have been attending to business for up to two years to date; 29.41 per cent have returned to ordinary home life, and only 20.58 failed to show benefit. One in advanced cachexia died and another after an operation for appendicitis. The others are still under treatment.

Influence of Coffee on Sense Acuity.—In 2,500 observations on three persons, Allers, Freund and Prager found that black coffee had a more or less specific influence on the visual field, the direction of the influence varying with the natural reaction of the subject. The normal tendency to exaggeration of peripherally seen movements was increased or decreased; the visual field was enlarged or contracted. One of the three subjects had the visual field contracted by 20 degrees or more outward, and by 10 degrees both in the upper and lower halves. The pulse was also extremely retarded in this case. The second subject had the visual field enlarged by 10 degrees. In the third, it was unmodified. In both the latter, the pulse was accelerated. It seems probable, though not certain, that the retina itself is the structure affected by the coffee. The tests were made with a cup of black coffee made from about thirty coffee beans.

The Structural Plan of Birds and the Flight Problem.—Groebbels weighed and measured forty-six species of birds. He found that a comparison of body weight and wing surface did not help to elucidate the problem of flying capacity, nor did the comparative weight of the muscles used in flying. The narrower the wing in comparison with its length, the greater is the flying power. In all the species examined, the anterior plus the posterior margin of the wing measured the same as the span of the wings. In the best flyers the measurements of the anterior wing margin, posterior wing margin and one-half the span of the fully expanded wings were exactly or approximately equal. In the proportion in which the posterior wing margin exceeds the anterior in length, is the flying power lessened The longer the body in comparison with the length of the outstretched wing, the less is the flying power. In those birds which utilize the wind for flight, definite relations exist between the measurements of span and contours when the wing is partially, as well as wholly, expanded. Measurements made on the winning craft in a flying contest illustrate the applicability of these laws to aircraft construction.

Gastric Secretion and Diuresis.—Arnoldi and Schechter gained the impression that subjects with hyperacidity have a larger renal excretion of water and solids and a stronger movement of the fluids and solids through the body, a stronger action of the liver and a weaker of the pancreas than normal subjects. There are analogies with diabetes, including a lowered utilization of sugar. The changes are the opposite in subacidity.

Pregnancy Glycosuria.—Adlersberg and Porges found in eight of fourteen pregnant women an increased permeability of the kidneys for dextrose. Two had a lowered sugar tolerance, resembling diabetes. After from two to five days of a diet free from carbohydrates, the experimental hyperglycemia and glycosuria were more pronounced. They suggest to use this method in tests for pregnancy.

Serologic Tests for Cancer.—Volkmann had good results with various modifications of the Abderhalden test in genital carcinomas.

Perineal Lacerations.—Henkel regards a timely episiotomy as the best means for prevention of rupture and prolapse. It may be sutured even on the second or third day and heals rapidly because the perineum has not been exposed to prolonged pressure, and because the wound edges are smooth.

Ectoscopy.—Weisz determines the margins of the lungs by inspection. The lower border may be seen in shallow breathing or even during the interval of respiration by the intercostal grooves. A sniffing movement makes them still more evident. No grooves are apparent in the spleen and liver region. With speaking (saying, for example, repeatedly the word kitt), the grooves bulge. This applies even when there is effusion. A point for puncture of an encapsulated empyema may be found by this symptom even if the rest of the pleura is thickened.

Familial Pernicious Anemia.—Tscherning observed pernicious anemia in three sisters.

Experiments in Regeneration of Pituitary. Meuret and Junker.—p. 194.
*Lymph from Thoracic Duct as an Antidiabetic. W. J. Klug.—p. 210.

Involution, Fibromatosis and Cancer of the Mammary Gland.—Dietrich studied the physiologic changes in the mammary gland from infancy to senility, and points out that these changes throw light on the nature of diffuse fibromatosis with cyst formation (cystic breast, chronic cystic mastitis, cyst adenoma). The source of this condition is neither inflammation nor tumor, but a condition of chronic irritation, arising from disturbed metamorphosis. Diffuse fibromatosis is accompanied by active proliferation of connective tissue, involutional processes and proliferation of epithelium, the final stage of which is represented by tumor formation (fibroadenoma and carcinoma). The frequency of carcinoma in cases of diffuse fibromatosis coming to operation is given as 40-50 per cent.

Operative Reduction of the Suprarenal Tissue in the Treatment of Inoperable Carcinomas.—Studies on the physiology of the reticulo-endothelial system, made in Stephan's service, showed the prime importance of this system in combating invasion, whether by infection, toxins or carcinoma. Further experiments showed that the function of this system is subject to an inhibiting influence by the internal secretion of the suprarenal cortex. Stephan conceived the idea that the benefit in carcinoma cases from deep roentgen-ray treatment lay chiefly in enhancing the defensive function of the connective tissue cell and that the refractoriness of certain carcinomas to the roentgen ray depended, not on the nature of the tumor cell or on the dose, but on defective function, with inability to respond, on the part of these cells. As the reticulo-endothelial system forms a single apparatus, progress must lie in improving the functional condition of the system as a whole. From this standpoint, he removed the left suprarenal capsule from eleven patients in late stages of inoperable carcinoma, which had proved absolutely refractory to the roentgen ray. Subsequent roentgen-ray treatment was followed by a severe reaction, although the doses were much smaller than those of the previous, reactionless treatment. The only pathologic change observed in the organ removed was atrophy, of varying grades, of the cortex, limited to the outermost zone. This was present in all but one case. Stephan holds that this atrophy represents nature's effort to increase the resistance by lessening the output of the hormone which inhibits connective tissue cell function. In the case in which atrophy was absent, the course of the disease was in keeping with the nonresponse of the organ. Stephan also reports good results from partial suprarenalectomy in cases of polycythemia, and temporary results from implantation of suprarenal tissue in cases of pernicious anemia. A measure for the functional power of the reticulo-endothelial system is found in the ferment number of the proteolytic serum ferment. Extirpation of a suprarenal capsule is to be regarded as an auxiliary, not an etiotropic therapy of malignant disease. His entire material, extending over years, will shortly be published.

The Lymph from the Thoracic Duct as an Antidiabetic.—Klug ascertained experimentally that the lymph from the thoracic duct contains a substance which interferes with consumption of sugar in the organism. Its nature is uncertain. He injected this lymph intravenously into three pancreatectomized dogs, and found that the blood sugar index sank; the level to which it sank varied in the different dogs. The result was the same whether autogenous or homogenous lymph was used. With a large initial dose the effect appeared to last through the day; a smaller dose had to be repeated. The action of the lymph seemed to be similar to but not so rapid or so strong as that of insulin. The quantity required is much larger and it is more difficult to obtain.

Jahrbuch für Kinderheilkunde, Berlin

112: 111-236 (April) 1926

*Nitrogen Metabolism in Fever. O. Beck.—p. 184.
Psychotherapy for Hysterical Children. J. Schlesinger.—p. 218.
"Fatty Acids and the Intestine." Catel and v. Graevenitz.—p. 227.

Pneumococcus Immunity.—Gutfeld and Nassau injected suspensions or autolysates of pneumococci intracutaneously. A positive reaction was induced in about 17.5 per cent of the infants under 3 months of age and in 92 per cent up to the end of the first year. The reaction was always negative in infants with acute bronchopneumonia. The serum from children with a negative reaction neutralized the suspension.

Vitamin C in Human Milk.—Frank observed recovery from scurvy in an infant and prevention of it in others, although the guinea-pigs fed with the same (human) milk died from scurvy.

Nitrogen Metabolism in Fever.—Beck investigated the nitrogen metabolism in six infants with fever due to vaccination, measles or chickenpox. The balance was negative, the elimination of uric acid and especially of ammonia was high, the amino-acids low. Creatinin did not change.

Leukocytes and Autonomic System. E. F. Müller.—p. 716.
Artificial Mineral Waters. O. Warburg.—p. 734.
Artificial Karlsbad Salts. F. Umber.—p. 734.

Insulin-Resistant Diabetes.—Frank sees an analogy to insulin resistant diabetes in the comparatively high resistance of glycosuria due to piqûres or epinephrine. It seems further that there may be combinations of nonpancreatic hyperglycemic diabetes with a renal glycosuria.

Treatment of Asthma.—Storm van Leeuwen and Kremer treated eighty asthma patients in special clean and airtight rooms supplied with cleaned air. They noted an almost complete cure of the asthma in 76 per cent, great improvement in 14 per cent, and no effect in 10 per cent. They investigated the probability of food factors by ordering a two day fast. The allergen-free room might be tried in treatment of eczema. They have already had encouraging results in treatment of some tuberculous subjects who are frequently allergic to substances contained in the air.

Syphilitic Diseases of Vessels.—Jungmann and Hall noted in the pathology institute of the Charité at Berlin an almost threefold higher incidence of syphilitic aortitis in the last five years than before.

Latent Edema.—Guggenheimer and Hirsch injected intracutaneously a solution which was isoionic with the blood. It disappeared faster in manifest and latent edema than in normal persons.

Excochleation of Bones.—Koolman believes that excochleation of the marrow of a long bone in dogs is followed after a negative phase by an increase of the erythrocytes above the original level.

Complement Fixation. P. Moretti.—p. 758.
Endocrine Diseases. H. Bernhardt.—p. 758. C'cn.
Milk Supply. H. Selter.—p. 763.

Serology of Mother and Fetus.—Hirszfeld and Zborowski find that fetuses of the AB group (IV Jansky) are born from mothers of the O (I Jansky) group and fathers of the AB group less frequently than expected according to the laws of heredity. They believe that perhaps a man of the pure formula AABB might not have any children at all with a woman of the group O.

Peroral and Percutaneous Immunization.—Reiter and Kurokawa found sodium benzoate a valuable addition to peroral or intracutaneous vaccines in animals.

Irradiated Milk.—György succeeded in treatment of rickets with irradiated dried milk.

Fatal Blunders in Otorhinolaryngology.—Zange warns against treating a supposed laryngitis for more than six weeks without consulting a specialist. A carcinoma might be overlooked. Syphilis is a frequent source of diagnostic blunders. It may resemble peritonsillitis and be neglected or maltreated surgically. It never causes trismus, while even a slight peritonsillitis is associated with difficulty in opening the mouth. Meningitic symptoms should always draw attention to the ear; so should slight rises in temperature in persons who have had inflammation of the middle ear at any time.

"Pregnancy and Leukemia." G. Joachim.—p. 603.

Urobilinogenuria.—Schiller found no urobilinogen in the hematomas of women with ruptured extra-uterine pregnancy, although they eliminated the chromogen by the urine. Bilirubin was present in the extravasates. Intravenous injection of sugar (0.25 Gm. per kilogram of body weight in 25 per cent solution) was followed by a decrease in urobilinogenuria in the first months of pregnancy, by an increase in the later months.

Protein Injections and the Neutrophils.—Hirsch finds a parallelism between the changes of leukocytes, especially the shifting to the left, after parenteral injections of proteins and in infectious diseases.

Cerebral Dyspnea.—Hess and Pollak examined the brain in dyspnea not associated with cyanosis. In such cases of various origin (diabetic coma, grave insufficiency of the liver from atrophy or cancer, pernicious anemia, atherosclerosis and encephalitis) the pigmented cells in the locus coeruleus were swollen and degenerated. They conclude that the locus coeruleus is the center for nervous regulation of breathing in man.

Contusion Injuries of Abdomen. R. Demel.—p. 480.
Crooked Back and Posture. J. Hass.—p. 481.
Theory of Diabetes. L. Pollak. Supplement.—pp. 1-16.

Skin and Pleura.—Sorgo observed an increased succulence as well as adherence of the skin of the chest when the pleura was affected by chronic processes. This is due to a stagnation of lymph, which drains normally the subcutis and muscles along the costal pleura. The absence of these symptoms indicates a free pleural cavity. An artificial pneumothorax is possible in such cases. He also uses the symptom in diagnosis between apical pleurisy and apicitis.

Precipitinogen and Toxin.—Eisler and Kovács conclude that the precipitate produced by an antiserum in filtered cultures of a hemotoxic cholera strain only adsorbs the toxin. They were unable to precipitate the toxin by its antitoxin.

*Brain Emulsion for Treatment of Epilepsy. V. Militzyn.—p. 426.
Postoperative Complications with Inflammation of Biliary Apparatus. I. Rufanoff.—p. 438.

Pathogenesis of Hemorrhagic Diathesis with Liver Disease.—Smotroff never found retarded blood coagulation or other signs of a hemorrhagic constitution in grave mechanical jaundice, unless there were diffuse lesions of the liver parenchyma. A deficient formation of thrombin is responsible for the faulty blood coagulation with diffuse lesions of the liver. The products of liver autolysis seem to inhibit the coagulation process. Lesions of the liver parenchyma are a secondary factor in the hemorrhagic diathesis, since experimentally it can be induced only by a combined injury to the liver and other tissues. In infectious jaundice, symptoms of a hemorrhagic diathesis as in hemorrhagic purpura may coexist with a normal number of blood platelets. Examination for signs of a hemorrhagic diathesis should be made in all patients with jaundice and liver disease, before operation.

The Endocrine Glands and Involuntary Nervous System in Syphilis.—Vasilieva noted enlargement of the thyroid gland in three of forty-two syphilitics, whether the syphilis was latent or in the secondary or tertiary phase. Atropine tests revealed a reduced sympathetic tonus, with vagotonia, in thirty. This testified to disturbances of the endocrine glands from the syphilitic infection. The phenomena disappeared after a prolonged specific treatment.

Brain Emulsion in Treatment of Epilepsy.—Militzyn applied brain emulsion in treatment of sixty-nine patients with grave epilepsy, rebellious to the usual measures. A daily dose of 1 cc. was given subcutaneously for thirty days, the series repeated at intervals of a month. No less than three series of injections were given. An improvement of sleep, appetite and mental condition was manifest in all. The number of seizures and their intensity became reduced in 92.7 per cent. The seizures appeared rarer in 38.8 per cent. The action on the mental faculties was particularly evident in one epileptic infant, aged 9 months. This treatment may prove effectual in prevention of dementia in epileptic children. The injections seem to be harmless; no by-effects occurred even after nine series.

13: 361-406, 1926

*Tetany and Alkalosis. J. G. F. de Geus.—p. 361.
*Skin Reactions in Scarlet Fever. Gorter and de Korte.—p. 383.
*Vaccination and Measles. J. Munk.—p. 399.
*Blood Transfusion in Infants. J. Slooff.—p. 402.

Tetany and Alkalosis.—De Geus' research on twenty dogs confirmed that tetany invariably develops when the calcium content of the serum falls below 8 mg. per hundred cubic centimeters. With a calcium content above this, tetany does not develop unless there is an excess of sodium present. Alkalosis alone does not induce tetany, and the phosphate ion does not seem to have any influence on its development.

Skin Reactions in Scarlet Fever.—Gorter and de Korte explain the differences in the behavior of diphtheria and scarlet fever toxins, and urge that conclusions from one cannot be applied to the other. In the filtrate of streptococcus cultures there is evidently something which has to do with scarlet fever, but this "something" is not a toxin. The filtrate of the culture, however, contains the virus of scarlet fever, and this multiplies in the culture. The blanching and neutralizing action of certain normal serums suggests that one antigen forms antibodies for the other, and vice versa. The invisible diplococci cultivated by Caronia on culture mediums free from streptococci, may be associated with the streptococci in the cultures of the latter. Skin reactions and active immunization have been realized with the Caronia microorganisms.

Measles During Vaccination.—Munk reports that a healthy child contracted measles the fourth day as her vaccination pustule was healing normally. The vaccinia flared up, and ulcers formed on the arm and trunk, with gangrenous centers. A vaccinia pustule developed on the other arm which ran a fourteen day course, as if there had been no immunization. The intercurrent measles seemed to have robbed the organism of all its defensive forces. In another child the eruption from intercurrent measles was most intense in the region of the pustule from the vaccination four days before the exposure to measles, but the ordinary course of the pustule was not modified. In two sisters given toxin-antitoxin preventive treatment against diphtheria, the eruption of an intercurrent chickenpox appeared first and was most pronounced in the region of the toxin-antitoxin injection.

Blood Transfusion in Treatment of Nutritional Disturbances in Infants.—Slooff's experience encourages blood transfusion as a routine measure in malnourished infants, especially when the child has to be restricted to water. In five instances described, the atrophy was of different origins, but the benefit from the transfusion was remarkable in the cases in which the vital energies were not at too low an ebb. In Gorter's experiments on rats, he was able to prevent or cure the atrophy from exclusive starch feeding by giving cod liver oil or yeast. In the infants whose cases are related there was no lack of vitamins; they seemed unable to absorb them from the intestinal tract, damaged by bacterial products or toxins. They were able to utilize those in the transfused blood, however, reaching the blood without having to pass through the intestinal walls. The transfusion may also bring antibodies for bacteria or toxins. Gorter succeeded in warding off keratomalacia and paresis in animals by injection of plasma alone.

Carolus Clusius, 1526-1609. B. W. T. Nuijens.—p. 979.

Hay-Fever.—Benjamins, Idzerda and Uittien made extracts of forty different kinds of plants in the Utrecht district that could be incriminated for hay-fever but tests reduced the number to six, and a polyvalent preparation made from this group has proved very successful and convenient. They warn that hay-fever is often assumed when merely spastic rhinitis is involved. There was an urticaria and pruritus or edema general reaction in two cases. The patient should be kept under supervision for half an hour after each subcutaneous injection, with epinephrine ready in case of by-effects.

Pituitary Extract in Obstetrics.—Muller remarks that much harm has been done with pituitary extract in childbirth, but analysis of such cases shows that the indications for and against it were not properly heeded.

Ether Anesthesia.—Schoorl insists that a bottle of ether once opened and standing around for a week, possibly exposed to the action of light, is not fit to use for general anesthesia.

Hemorrhage in the Retina After Transfusion of Blood.—Schaly encountered in 1925 three cases of impairment of vision soon after blood transfusion, which had been done on account of pernicious or aplastic anemia. In one case the eyes had been examined just before the transfusion, and there was no trace of hemorrhage. In one case the eyes were examined post mortem, confirming the extent and the irreparable nature of the disturbances. Vision is not impaired until the extravasated blood spreads toward the macula.

Fames Canina.—Schrijver reproduces the title page of three theses presented for the medical degree about 1660. The clinical picture described as fames canina was evidently an ulcer in the pylorus region, with dilatation of the stomach from stenosis, before the days of the stomach pump.

Mededeel. v. d. Dienst d. Volksgezondheid, Batavia

*Rabies Department. J. van den Hoven van Genderen.—p. 115.
Bacteriologic Department. L. Kirschner.—p. 131.
Serum Department. P. Papamarku.—p. 145.

Vaccine Production in the Dutch East Indies.—Three kinds of animals are used in the preparation of vaccine against smallpox, rabbit, calf and buffalo, with retrovaccination from calf to rabbit and from buffalo and vaccinated subject. For preservation of the virulence of the virus in the tropics, the vaccine virus has to make thus a kind of circular movement. This technic has proved efficient, and the vaccine institute at Weltevreden despatched lymph in 1925 for more than twelve million inoculations. It aims to vaccinate the entire population of the islands, and revaccinate every ten years. Means to realize this more effectually are discussed.

Treatment of Rabies.—The Antirabies Institute uses the Högyes method, and this report states that fixed virus emulsified in glycerin diluted 25 per cent with normal saline solution retains its original virulence for more than a year when kept at from minus 10 to minus 15 C. Exceptionally fine and completely sterile emulsions are obtained by Nijland's method of shaking up the brain tissue, transferred directly from the skull to a small wide-mouthed bottle of thick glass, a quarter filled with glass beads. After adding some normal saline solution, the bottle is plugged and shaken by hand or with a small electric shaking apparatus.

Hospitalstidende, Copenhagen

69: 197-216 (March 4) 1926

*The Static Leukocyte Reactions. E. Jacobsen.—p. 197.

Leukocyte Reactions.—Jacobsen has confirmed Jørgensen's statements that the number of leukocytes in the peripheral blood capillaries changes on a change from the reclining to the erect posture. Jacobsen did not find the differences so great as the latter found, but they were unmistakable, sometimes over 20 per cent in blood from the finger as well as from the ear. To eliminate error from muscular strain, he fastened the subject to a table and tilted the table as desired. The data seem to testify that the changes are due to the heart and are not of peripheral origin. In two subjects with actual heart disease the blood in the ear and the finger blood did not parallel each other as in the twenty-two other subjects. The data all testify in favor of a central (cardiac) origin for the static leukocyte reaction.

*Formation of Gallstones in the Liver. S. Hansen.—p. 217.
Experiences with Transfusion of Blood. O. Kapel.—p. 228. C'td.
*Diagnostic Eversion of Rectal Mucosa. O. Jersild.—p. 234.

Gallstones in the Liver.—Hansen states that gallstones were found in 24.7 per cent of 392 adult cadavers examined in 1925 and two or more gallstones were found in the liver itself in seven, the ages from 68 to over 80. In six of the cases the bile ducts were more or less obstructed but in one man of 80 small, pure pigment calculi were found in the liver and also in the gallbladder and cystic duct. The bile was sterile, and nothing was found in the anamnesis or at necropsy to suggest stasis of bile at any time. In some of the others there was cholesterol with the pigment in the intrahepatic calculi. Some of the intrahepatic calculi were faceted, which disproves the theory attributing faceting to the pressure of the gallbladder. In conclusion he refers to J. Hoffmann's Geneva 1912 thesis on Intrahepatic Calculosis and E. Beer's study published in 1904 in the *Archiv für klinische Chirurgie* as the only literature available on the subject.

Diagnosis of Gonoccal Disease of the Rectum.—Jersild states that it is possible, with one or two fingers in the vagina, to evert the mucosa of the rectum in 60 or 70 per cent of adult women. This allows direct visual inspection of gonococcal proctitis which often escapes examination otherwise, owing to the folds and crevices. This eversion method smooths out the folds and brings enough of the mucosa into view to confirm the diagnosis, and possibly reveal an unsuspected fissure.

*Function of the Static Labyrinth. S. H. Mygind.—p. 337.
*Exophthalmic Goiter. C. Gram.—p. 345.
Double Ampule for Arsphenamine. Philipsen.—p. 349.
*Measles Convalescent Serum in General Practice. T. Kemp.—p. 351.
The Mode of Life and the Mortality. M. Hindhede.—p. 356.

The Functioning of the Labyrinth.—Mygind's profusely illustrated article presents arguments to sustain the contention that the static labyrinth is a part of the skin, with its corresponding nerve. The stimulus for it is a contact sensation, and its function is a contact-seeking reflex. The direction of the reflex is determined by the location of the irritated point in respect to the three dimensions of the space. He shows how this assumption explains the phenomena of past pointing and other vestibular reflexes.

Exophthalmic Goiter.—Gram gives some illustrations of an antique bust and modern cases of exophthalmic goiter, calling attention to the likeness between them. There do not seem to be any references in ancient literature to this disease, but some of the Roman sculpture suggests it. He thinks that treatment of exophthalmic goiter should be preeminently addressed to the mind. For this reason he urges a stay in a sanatorium or, better still, in a hospital. The change of scene in itself brings a rest from the daily discomforts or worries that have been instrumental in bringing on the disease, and the patient experiences great relief in talking things over with a bright, solicitous nurse. The general care in the hospital reduces or cures dyspeptic and other symptoms which have worried the patient. In addition to psychotherapy, he gives iodine and iron pills, outdoor rest cures, and if there is much agitation, sodium bromide, valerian, camphor or digitalis as indicated. The extremely toxic cases belong to the surgeon and iodine is strictly contraindicated. Roentgen exposures are also useful in checking thyroid function, but *there is danger of accomplishing too much with it, entailing* myxedema from thyroid insufficiency. Exophthalmic goiter has been known exceptionally in girls, and even in boys, before puberty.

Measles Convalescent Serum in Prophylaxis.—The three children, all under 5, slept in the same room with the father who had contracted measles. The children were all in the midst of whooping cough, and the sixth day of the father's measles they were injected intramuscularly with 10 or 15 cc. of convalescents' serum. None developed measles. The father, Kemp adds, donated serum when he was convalescent, to aid others in prophylaxis, and Kemp urges practitioners to aid in finding older children and adults willing to yield serum for the purpose.

Insurance Against Disability and the Campaign Against Tuberculosis. J. Frandsen and O. Bruun-Rasmussen.—p. 421.

Innervation of the Stomach.—Thomsen recalls that the innervation of the stomach consists of motor, inhibiting and secretory fibers in the vagus and sympathetic, besides the autonomic, intermuscular, Auerbach, and the submucous, sympathetic, Meisner nerve cells in the stomach walls. The left vagus dominates the secretion in the stomach; this was demonstrated anew by his cure of a man with gastric crises and periodic attacks of continuous hypersecretion so debilitating that operative relief was imperative. The man was restored to clinical health by resection of the vagus ramifications on the anterior aspect of the abdominal portion of the esophagus. The innervation of any organ cannot be regarded as an isolated phenomenon but only as an integral part of a great closely interlinked system. The local manifestation in the stomach is a result of nervous coordination. The effect of this coordinating work is most readily manifested in the secretory domain; the motor function responds more sluggishly.

Local Injection Treatment of Varicose Veins.—Alstrup has the patient stand on a footrest nailed to a long board standing upright. This allows injection in the erect position. An assistant then tilts the board over a saw-horse until the patient's head is lower than the feet. This seesaw apparatus leaves the operator's hands free all the time; the patient is still and tranquil, and the injection of the sodium chloride solution proceeds smoothly.

Correction

Neutral Red Serologic Test for Cancer.—Roffo's original technic for this test was with 2 cc. of serum to which were added 5 drops of a 0.03 per cent solution of neutral red. His latest publication gives the technic as 2 cc. of serum with addition of 5 drops of a 0.1 per cent solution of neutral red. This corrects the abstract on page 1877. His original communication was summarized, Feb. 13, 1926, p. 519.

THE INFLUENCE OF UROLOGY ON LONGEVITY *

B. A. THOMAS, M.D.
PHILADELPHIA

The pessimistic Euripides states that "not to be born is best, and next, to die as soon as possible." Unfortunates, therefore, as human beings we exist, irrespective of our responsibility for our presence; but, contrary to the philosopher's advice, it seems to be a fundamental trait of human nature to want to live as long as possible, and man and medicine have ever striven to promote the public health and lengthen the span of life.

What should be the normal span of life? Dr. Darlington[1] tells me it is very doubtful whether the prevalent idea of three score and ten years, taken from the prayer of Moses,[2] should be our goal, since there is better biblical authority[3] "that a man's days shall be a hundred and twenty years," that every one dies prematurely, that no one dies of old age, and that even Methuselah, the oldest man, was drowned in the flood. That life expectancy has been and is steadily being lengthened is well supported by the investigations of preventive medicine and applied sanitary science. Indeed, it would appear from Carrel's experiments that cells are immortal; and recent studies with foods, vitamins and enzymes in animals indicate that the duration of life may be tripled. Apropos of longevity in the past, present and future, it is significant to note that for centuries before and after the time of King Tut, down to the discovery of America, the average length of life was eighteen years; at the time of the French Revolution it had increased to 33 years; at the time of our own Civil War it had advanced approximately to 45 years; at present it is about 57 years, and the longed for 70 may be reached within the next fifty years, maintaining the present ratio of medical progress.

What are the factors that have contributed most toward this remarkable improvement in vitality? In their order of importance they may be stated to be: (1) medical research and discoveries, e. g., vaccination against smallpox, bacterial origin of diseases, transmission of disease by vermin and insects, animal experimentation, study of anatomy, discoveries relative to tuberculosis, syphilis, diabetes and nephritis; (2) preventive medicine, including personal hygiene, sanitation, public health organizations and life extension centers, and (3) advances in medical and surgical diagnosis and treatment, particularly specialism and group clinics.

It is well known that the annihilation of certain of the scourges, epidemics and famines that were visited on mankind in ancient and medieval times played the most important rôle in materially lengthening life expectancy. It is also true that most of the twenty years added to longevity during the past century is the result of child hygiene and reduced mortality up to the age of 5. However, ten of these added years have been contributed during the last two decades, and I am not at all inclined to attribute the result entirely to preventive medicine. Unfortunately, figures are not available, nor can they be compiled at present, to show the part actually played by the marvelous advances in clinical medicine and surgery so far as the conservation of health and life is concerned. There are many reasons to indicate why life has been prolonged ten years in the past twenty or thirty, although only recently has there been a gain in life expectancy at the age of 50. Among impaired lives between the ages of 40 and 60, there has been a mortality reduction of 67 per cent. Obviously, it is just as impossible today to state in figures the proportionate rôle played by urology and clinical medicine as it is to compare accurately preventive and clinical medicine so far as their influence on longevity is concerned. That urology has exercised a definite important influence certainly cannot be denied, particularly in remembrance of the fact that, in the entire realm of medicine, there is no part or specialty in which diagnosis and treatment, by virtue of new inventions and discoveries, are more precise, satisfactory and complete.

In what respects has urology played its rôle and been an important factor in the prolongation of life?

The history of urology is one of the, if not the, most interesting and fascinating in the whole progress of medicine, and has been well portrayed by Gross,[4] the greatest of American surgeons and father of American urology, Smith,[5] Guiteras,[6] Young,[7] Martin,[8] Moore[9] and others. The names of Bossini, Civiale, Bright, Rayer, Simon, Hunter, Désormeaux, Thompson, Gross, Van Buren, Bigelow, Mercier, Guyon, Maisonneuve, Nitze, Casper, Israel, Brenner, Kelly, Rovsing, Otis, Brown, Albarran,[10] Richter, Zuckerkandl, Keyes,

Belfield, Voelcker, Cathelin, Chute, Cabot,[11] Cunningham, Young, Lewis, Squier, Buerger, Gunner, Geraghty, Legueu, Marion, Chevassu, Papin, Hinman, Kretschmer, Quinby, Bugbee, Caulk,[12] Braasch and many others represent strides in the development of our specialty, from the days of old when it represented all genito-urinary diseases, until its recent coronation as urology. Each recalls inventions, discoveries, research or valuable additions to surgical technic that have promoted the successful treatment of diseases of the urogenital tract, rendered surgery safe and ever safer for humanity, reduced mortality, and thereby lengthened longevity. Schmidt[13] rightly observes that progress in urology is to be measured by outstanding scientific discoveries and their influences rather than by dates or periods. Thus, by the invention of the urethroscope and cystoscope, instruments that have revolutionized urology in the last fifty years, the results, directly, in our specialty—namely, the visualization and accurate diagnosis even by photography and biopsy, if necessary, and treatment of lesions of the urethra and bladder; catheterization, diagnosis and differential diagnosis and treatment of kidney diseases; pyelography and ureterography; dilation of the ureter for strictures and calculi; intravesical operations, as ureterotomy, excision of bars, removal of foreign bodies, fulguration of tumors and implantation of radium—have been far reaching and almost incredible, and have exerted a truly incalculable effect on mortality reduction. Indirectly, we see daily the influences of the endoscope and cystoscope in many other specialties, as the pharyngoscope, bronchoscope, gastroscope and proctoscope.

Other milestones in the development of urology that deserve especial mention and have made possible its present state of excellence, whereby urologic diagnosis and treatment have been materially refined, morbidity reduced and mortality greatly lowered, are the discovery of the germ origin of disease, surgical antisepsis and asepsis, for without the latter cystoscopy and ureteral catherization would not have been tenable; roentgenology as applied to urology, including cystoradiography, ureteroradiography, pyeloradiography and pneumoradiography; epoch making researches and discoveries in pathology and bacteriology; functional kidney diagnosis; blood chemistry; immunology; serology, chemotherapy; diathermy and narcosis as applied to local infiltration, and the various modalities of spinal anesthesia.

Improvements in surgical technic, including preoperative and postoperative care of patients, have resulted in a tremendous conservation of life. For a full appreciation of this fact, a brief review of the past and present operative results for the more important genito-urinary diseases should be convincing. Deaths in Philadelphia from 1916 to 1925 inclusive from all causes decreased from 1,615.72 to 1,316.13 per hundred thousand, or 18.5 per cent; during the same period, for genito-urinary diseases alone, the decrease was from 175.81 to 129.69, or 26.2 per cent. This is a very commendable comparative showing for genito-urinary diseases, and seems to be in conformity with the progress of the specialty the last seventy-five years, as I shall try to show.

The treatment of stricture of the urethra by dilation is of great antiquity, and even today among the Thlinket Indians of Alaska and British Columbia in certain localities, employing a willow stick, constitutes the only method. Although Paré, in the sixteenth century, improved the technic of stricture operations, and Wiseman did the first external urethrotomy in 1652, and Physik produced his "stylet" for cutting strictures in 1795, treatment by cauterization and bladder puncture by the rectovesical, perineal and suprapubic routes as late as 1855 was practiced, with a mortality of from 7 to 11 per cent. This would have been much higher if cases of periurethral abscess, extravasation of urine and fistulas had been included. In 1908 the advancement in the treatment of stricture is well represented by the statistics of Watson and Cunningham;[14] namely, 0.5 per cent for gradual dilation, 1.1 per cent for internal urethrotomy, and from 1.56 to 4.9 per cent for resection or combined internal and external urethrotomy.

The best figures for orchidectomy in the past, for testicular tumors, are 19 per cent cures in the collected statistics of Chevassu.[15] Recently, Hinman has reported 35 per cent for his radical Wertheim operation.

Smith, in 1855, referring to the operation of Gross, who revived and successfully performed, eight times, the old operation of Celsus for varicocele, asserted that there was less risk of erysipelas of the scrotum than from Velpeau's operation, while the "compression method of Breschet resulted in death in several instances." Today the operation is a simple affair with practically no mortality, and varicocele is no longer even an absolute disqualification for military service.

A few decades ago, Segond reported a mortality of 29.8 per cent in 114 cases of abscess of the prostate. It is difficult to correlate this with the extremely low—less than 5 per cent—death rate at present.

Although Cole in 1884, in America, was first to perform prostatectomy (perineally), it remained for Belfield, [illegible] Gill, Goodfellow and Fuller to establish the [illegible] on a firm basis. As late as 1887, T[illegible] stated that successful prostatectomy was [illegible] In 1886, Ashhurst[16] said "There is nothing [illegible] ue surgically, nor is excision a procedure to [illegible] vocated"; also, when complicated by calculus, [illegible] lithotomy or lithotrity be done, regard should be had to the possibility of removing both of these causes of annoyance by the same operation." In the light of our present knowledge, is it any wonder that up to twenty years ago the death rate ranged from 15 to 50 per cent, whereas today Young reports 3.4 per cent, Freyer 5.5 per cent and Liebig 7.4 per cent in the collected statistics of 7,565 operations, suprapubic and perineal? Forty years ago, Ashhurst spoke very skeptically of the treatment of median bars, although section had been practiced and recommended by Guthrie, Mercier, Teevan and Gouley. Today Young reports a mortality of 2 per cent in 355 punch operations, while Caulk reports no deaths at all from his cautery punch, and says that "30 per cent or more of obstructions can be relieved by this method, thereby reducing the number of prostatectomies, and lowering the general mortality rate of prostatic surgery."

In 622 cases of intraperitoneal and extraperitoneal rupture of the bladder, Watson and Cunningham, in 1906, found a mortality of 88 per cent from palliative and 46.7 per cent from operative treatment; today, the operative death rate should not exceed one tenth of this.

[16] Ashhurst: International Encyclopedia of Surgery **6**, 1886.

During the last thirty years, the death rate from diverticulum of the bladder has decreased from 80 to 8 per cent.

Since the third century B. C., when Ammonius performed the first lithotripsy, and the dawn of the Christian era, when Celsus described the first lithotomy down through the middle ages, when attempts were made to dissolve stones by various agents from gastric juice to goat's milk, not to speak of the much vaunted concoction of the notorious Johanna Stephens, who swindled the British parliament out of £5,000, and in spite of the astonishing results of the great lithotomists, the Colots and Frère Jacques, who cut for stone more than 5,000 times and was finally exiled from Paris because most of his patients died, and Cheselden, who could perform the operation in fifty-four seconds, the mortality in Gross' time ranged from 11.4 to 50 per cent. In 1908, in 33,869 collected cases, in which operation was done suprapubically, perineally or by litholapaxy, Watson and Cunningham reported the death rates 13.2, 10 and 2.4 per cent, respectively. During the last twenty years, in the best American clinics, the mortality for cystolithotomy has been reduced to less than 5 per cent.

Until very recently, the treatment of bladder tumors, even papillomas, was both the nightmare and the despair of surgeons. The introduction of cystoscopic fulguration in 1910 by Beer revolutionized the treatment of benign tumors, and has lowered the mortality from this particular type of vesical growths, constituting the majority, practically to nil. Although the treatment of carcinoma of the bladder, by partial or complete cystectomy, roentgen ray, diathermy and radium, thus far, has been disappointing and has not measured up to our hopes, something has been accomplished. Symptoms have been relieved and life prolonged from a few months to one or two or more years, in many incurable cases, as compared with a 100 per cent death rate a few decades ago. In an analysis of forty-three patients of my own, 13.8 per cent lived from three to ten years, and 10.3 per cent were alive and free of symptoms. The operative mortality was approximately 10 per cent.

Ureteral implantation into the sigmoid after the Coffey-Mayo technic promises a far reaching influence in the reduction of ascending renal infections, at the same time rendering possible surgical extirpation of the bladder and other pelvic viscera, thereby immeasurably affecting longevity.

From the time of Hippocrates, 460-357 B. C., who first "operated for calculi of the kidney by incision," until 1869, when Simon performed the first successful nephrectomy for calculous pyonephrosis and presented his epochal monograph on the surgical affections of the kidneys, renal surgery received little attention. Ten years later, Pilcher could find only fifteen cases of nephrectomy in the literature. In 1885, Gross reported a mortality of from 20 to 60 per cent for pyonephrosis, tuberculosis and tumor. In 1912, Guiteras reported a mortality of 10 per cent for nephrotomy and 30 per cent for nephrectomy, and stated that in tumor it might reach 50 per cent. Today a conservative estimate of the death rate from nephrectomy is from 5 to 10 per cent. At the Mayo Clinic, in 863 nephrectomies for tuberculosis, the mortality was 2 per cent, while Young reports an operative mortality of only 0.89 per cent in 112 patients.

Time forbids the further presentation of data, especially that bearing on the reduction of the death rate in chronic nephritis, as the result of organized health center work. Enough, surely has been stated to show that thousands of lives have been prolonged and spared by the progress of urologic surgery, nor is it necessary or possible, accurately, to set down comparative statistics with other factors or fields of medical or surgical endeavor to substantiate the fact.

The most potent force that has enabled urology to exert its influence on longevity has been its recognition as a specialty, whereby the public and the general practitioner have come to appreciate the significance and importance of certain symptoms and indications, and realize the value of prompt investigations and expert procedures. No specialty has struggled harder than ours to throw off the mysticism, dogmatism, ignorance and superstition of the past, and today the spires of urology scintillate high and magnificently in the heavens of the medical world.

The present day cry of "overspecialization" is fraught with great danger, second only to the attempts to subjugate urology to general surgery. Statistics as long as the eye can reach can readily be produced to prove the fallacy of this contention. However, common sense and the elimination of selfishness are all that are required. Cabot has aptly said, "The best results will fall to the surgeon who supervises from beginning to end the investigation and who applies the remedy, rather than to the operator, who may be eternally confounded by the error of an assistant." Division of responsibility, ofttimes, is bound to affect the best welfare of patients.

Two factors that are doing most and are destined to produce the greatest benefits in the future, so far as urology and its influence for humanity and longevity are concerned, are: first, fundamental, systematic, broad graduate instruction and training of would-be urologists, qualifying them for special major surgery, not merely cystoscopy and venerology; and, second, the creation in our hospitals of special wards or departments for urologic surgery, with a personnel of residents, interns, nurses and orderlies trained and assigned, at least temporarily, solely to that specialty. Then and only then will the best results be obtained. It is already universally recognized and true for other specialties, as orthopedics, pediatrics, ophthalmology, obstetrics and gynecology. It must follow for equally good and better reasons for urology.

1900 Spruce Street.

Microbe of Oroya Fever.—Oroya fever, or Carrion's disease, is a highly fatal infection endemic in certain regions of Peru. Its most striking clinical feature is a rapidly progressing severe anemia, associated with febrile reactions. In the erythrocytes of patients suffering from the disease, Barton found, in 1905, peculiar bacilliform elements, the specificity of which has been confirmed by Barton's subsequent observations and those of later investigators. Strong, Tyzzer, Sellards, Brues and Gastiaburu concluded that these bodies are of protozoan nature and proposed for them the name of *Bartonella bacilliformis*. Inoculation of cultures of *B. bacilliformis* into young rhesus monkeys induced intermittent fever lasting many weeks. Typical endoglobular forms of *B. bacilliformis* have been demonstrated in the erythrocytes of these animals. Intradermic inoculation of the culture into the eyebrows gave rise to highly vascular nodules, resembling the nodules of experimental verruga induced in monkeys by previous investigators. *B. bacilliformis* can readily be recovered in pure culture from the blood, lymph glands, spleen and nodules, and passages from animal to animal are easily carried on.—Noguchi, Hideyo; and Battistini, T. S.: *Science* **63**:212 (Feb. 19) 1926.

CONNOTATION OF CONSTITUTIONAL PSYCHOPATHIC INFERIORITY WITHOUT PSYCHOSIS

A STUDY OF FIVE HUNDRED DIAGNOSES *

JAMES H HUDDLESON, M D.
NEW YORK

Approximately 7 per cent of case histories in the neuropsychiatric outpatient department of Veterans' Hospital 81, New York, reveal a diagnosis of constitutional psychopathic inferiority or some synonymous term, made once or oftener during the last six years by attending specialists of the Veterans' Bureau and its predecessor in this field, the United States Public Health Service The purpose of this study was to determine what diagnostic criteria were adducible in each case toward the conclusion that a constitutional psychopathy was present The findings of thirty-three neuropsychiatrists are recorded in the series of 500 alphabetically consecutive histories

Constitutional psychopathic inferiority without psychosis is employed here as a generic term to include the six classes of constitutional psychopathic states noted in the nomenclature,[1] viz, criminalism, emotional instability, inadequate personality paranoid personality, pathologic liar and sexual psychopathy (One more term, nomadism, is added to an otherwise identical list in a recent United States Army publication[2]) The Public Health Service nomenclature formally separates constitutional psychopathic state from constitutional psychopathic inferiority, but the apparent interchangeability of these terms has made strict adherence to their differentiation rather doubtful in outpatient examining work. This issue is avoided by the introduction and common use in the case histories of an ambivalent phrase, "constitutional psychopath" One frankly equivocal diagnosis appears as "C P I. state."

A careful attempt to differentiate between the two terms has been made by Visher[3] as follows: "Constitutional psychopathic state is differentiated from constitutional psychopathic inferiority by the presence of such morbid manifestations as lie in the immediate foreground of insanity. . . There is usually no history of marked industrial inefficiency or of antisocial conduct, and what gross maladaptation is present does not extend back to early life" Certainly this differentiation is difficult to make, even under the most favorable circumstances of study. Whether it is quite valid, e g, whether sexual psychopathy, one of the constitutional psychopathic states, can be separated from constitutional psychopathic inferiority and construed as not extending back to early life, is questionable.

"Constitutional inferiority" was first introduced into American psychiatric terminology by Meyer[4] only two decades ago. Karpas,[5] after describing "psychic constitutional inferiority" in 1913 as the foundation of most if not all the psychoses, subjected it three years later[6] to a more minute analysis. In this he subtracted the group of intellectual inferiors, and three subgroups of emotional inferiors (individuals with shut-in personalities, manic-depressive make-ups, and hysterical and neurasthenic temperaments), leaving one emotional subgroup (including the crank, psychopath or "congenital psychoneurosis") and a final group of volitional inferiors His discussion of volitional inferiority is chiefly concerned with delinquency. Goddard,[7] in 1921, carefully separated psychopathy with or without arrested development from arrested development alone. Two tendencies appear in the literature, first, toward distinguishing a class of psychotic and inferior personalities definitely from the mental defectives on the one hand and from the psychotics on the other, and, second, toward including progressively more of the delinquent types in this class

The table gives the incidence rates of twenty-one characteristics One finding of a given trait conditions a single entry, except for traits marked with the asterisk The counting of a trait in one of these starred groups may be duplicated in other starred groups; that is, such groups overlap.

Incidence Rates of Twenty-One Characteristics

Classes of Characteristics		Characteristics	Incidence in Number of Cases	Incidence in Each 100 Cases
Physical manifestations	*a*	Anatomic stigmas	40	8
	**b*	Sexual anomalies	21	4
	c	Enuresis (after age 5)	11	2
	d	Onychophagia	12	2.5
	e	Stuttering and stammering	46	9
Addictions	*f*	Drug addiction	8	1.5
	g	Alcohol addiction	50	10
	h	Tobacco addiction	11	2
Traits suggesting manic-depressive make-up	*i*	Emotional instability	318	63.5
Traits suggesting manic and paranoid tendencies	*j*	Grandiosity and excessive self-esteem	102	20.5
Traits suggesting paranoid trend	**k*	Paranoid personality	90	18
Traits suggesting schizophrenic make-up	**l*	Metatopomania	97	19.5
	m	Polypraxia	240	48
	n	Working beneath mental capacity	9	2
Traits suggesting mental deficiency	**o*	Poor cooperation and refractoriness	179	36
	**p*	Unreliability (other than *q* and *r*)	157	31.5
	**q*	Conscious exaggeration of symptoms	207	41.5
Conduct disorders	**r*	Malingering (charged as such)	28	5.5
		Malingering suspected	11	2
	**s*	Truancy and A W. O L. tendency	74	15
	**t*	Trouble making	95	19
	**u*	All conduct disorders	250	50

Taking up the characteristics in order, one notices, perhaps as a trend of the times toward rejecting Lombroso[8] and not yet assimilating Draper,[9] that anatomic features have received scant attention in the records of the psychiatric examinations surveyed. (*a*) Stigmas are noted in no more than 8 per cent of these case records, though they doubtless marked a considerably larger number of claimants. House[10] divides his constitutional psychopathic inferiors into two classes, roughly "static" and "dynamic," in both of which the stigmas of degeneracy show a high incidence. No one of the classes in the Public Health Service nomenclature is quite coterminous with either of those. Most of House's static cases can be considered inadequate personalities, and his dynamic ones may be distributed among the other classes.

To the small category of (*b*) sexual anomalies, 4 per cent, have been referred both feminine (all of these cases were of males) secondary sex characters, and habits of sexual perversion. (*c*) Enuresis, found in 2 per cent, when it accompanies other suspicious symptoms, is likely to be included in the evidence for a constitutional psychopathy; similarly (*d*) onychophagia, with an incidence of 2.5 per cent. Much of (*e*) stuttering and stammering is referred to hysteria; enough still remains to be noted as evidence of an inferiority in 9 per cent of the series. The proportion of cases that show (*f*) drug, (*g*) alcohol and (*h*) tobacco addictions, respectively 1.5, 10 and 2 per cent, is comparatively small. Tobacco addiction is understood to mean a pronounced and excessive, not a moderate, tobacco habit.

(*i*) Emotional instability, with the highest incidence of all, 63.5 per cent, is a trait or rather group of traits that recalls the milder types of emotional insanity and mental deficiency, as well as some hysterias and anxieties. The emotional instability belonging to inferiority differs somewhat from a manic-depressive make-up. The "constitutional psychopathic personality" is the more comprehensive conception; furthermore, it means something pathologic: a "manic-depressive make-up" describes a personality that is not necessarily pathologic so long as a psychosis is not superadded.

Emotional instability is common to various psychoneuroses as well; of these, transference neuroses are less readily confused with constitutional psychopathic inferiority than are the narcissistic states. An acquired instability may conceivably be based on a relatively stable make-up, and should not lead to a hasty conclusion of constitutional psychopathy. Again, instability is but one part of a symptom-complex, the diagnosis of which cannot be expected to rest on that finding alone. The emotional abnormality exhibited by a well marked epileptic personality, for example, can typically be distinguished from the constitutional psychopathic picture. Clark [11] points out that "if it be true that in essential or idiopathic epilepsy there is a more or less definite make-up, a character type of supersensitiveness, egotism, poor adaptability, and a certain defect in the power for development of the emotional life as contrasted with the intellectual equipment per se, then . . . the absence of these stigmas . . . should make us hesitate before finally committing ourselves to a diagnosis . . . of essential epilepsy."

(*j*) A grandiose tendency and exaggerated self-esteem, part of a manic make-up, appear in 20.5 per cent. (*k*) Paranoid personality is found in 18 per cent; many of these individuals, if sufficiently analyzed, would prove to be of prepraecox types corresponding to certain of the "schizoids" of Brill;[12] but since they have not developed psychoses they are habitually grouped here. He explains that "the expression 'schizoid,' which gives the picture of schizophrenia in extreme forms, . . . designates a type of psychic being and psychic reaction which exists in a more or less pronounced form in every person. . . . In predisposed individuals these reactions [syntonic or schizoid] may become markedly enhanced and then result in a psychosis of either type. . . . A great many of them never go beyond a certain point with their schizoid tendencies."

Though close to the simple praecox category, (*l*) metatopomania, the tendency to wander from place to place, and (*m*) polypraxia, a similarly habitual wandering from one occupation or place of employment to another, are not pathognomonic of a deteriorating psychosis. In this series they are found mentioned as evidences of psychopathic inferiority in 19.5 and 48 per cent of cases, respectively. In exceptional cases, 2 per cent, (*n*) employment at occupations beneath the mental capacity has assisted in making the diagnosis.

(*o*) Poor cooperation and refractoriness to treatment is a sufficiently convenient and important administrative concept to be recognized, applying, as it does, to more than a third (36 per cent) of the constitutional psychopathic claimants treated. It does not pretend to approximate a unit character, and is found as often in mental deficiencies, and paranoid and hypomanic states. (*p*) Unreliability is almost as prevalent (31.5 per cent), and is similarly ill defined and suggestive of mental defect.

(*q*) Conscious exaggeration, noted in 41.5 per cent, contrasts with (*r*) malingering, in 5.5 per cent. The latter term, on the authority of Jones and Llewellyn,[13] should include exaggeration when this is conscious; but malingering is a "crime," and diagnosing it puts a burden of proof on the examiner that he will not be expected to assume without considerable deliberation.

Next to emotional instability, some form of (*u*) conduct disorder understood in its broadest sense is the commonest characteristic found, appearing in exactly half of the cases. This group includes all of three others (malingering, [*s*] truancy, and [*t*] trouble-making) and parts of four more (sexual anomalies, unreliability, conscious exaggeration, and refractoriness to treatment). The habitual disturbers and trouble-makers, constituting 19 per cent of this series, must often be placed at the same time in the paranoid personality group. Truancy is not infrequent and would probably have appeared oftener if it had been practical to obtain social service histories in all cases.

The diagnosis of "constitutional psychopathic state, criminalism" has been very rarely made, and "delinquency" never. Evidently it has been usual to consider antisocial manifestations as contributing to certain neuropsychiatric symptom-complexes, rather than constituting a principal disease. This brings up the whole question of "moral imbecility" and the difference between legal, ethical, sociological, psychologic and medical conceptions of antisocial conduct, so well delineated by Tredgold,[14] and exhaustively debated by Stoddart,[15] Shrubsall [16] and Burt.[17]

If a diagnosis of "no nervous or mental disease, delinquency," "no nervous or mental disease" or "delinquency" alone is made in a case showing delinquent tendencies, the examiner will be clearly committed to the definite view that full responsibility exists. On the other hand, the diagnosis of "constitutional psychopathic inferiority" or "constitutional psychopathic state, criminalism" may be construed either as noncommittal, that is, a symptomatic diagnosis, or as committing the examiner to the conclusion that responsibility is relatively impaired because of the presence of a mental disease other than imbecility or psychosis; namely, constitutional psychopathic inferiority, then a [psycho] pathologic diagnosis.

In psychopathic inferiority with psychosis or with imbecility, irresponsibility may be referable to the psychosis or to the mental deficiency. Accompanying mental defect of the moron grade is frequent. Psychometric tests, made on many individuals in this series, show levels from that of a medium grade imbecile reaching the mental age of 5 (three cases), to that of a superior adult.

Crime to some examiners presupposes a morbid mental condition and therefore demands a medical diagnosis, though there is not quite that unanimity conceived of by Sands,[18] who holds that "the objective of all workers in the various phases of psychiatry is the consideration of all behavior disturbances as manifestations of a disease process, and the problem as medical." The including of "constitutional psychopathic state, criminalism" in the nomenclature does suggest that the case of an habitual criminal should not be diagnosed "no nervous or mental disease." Two such cases in this series have been called psychopathic on no other evidence than that of delinquency. The medical status of an occasional criminal is not necessarily settled. The question is still open whether all possible neuropsychiatric diagnoses of the case of a known criminal must be confined to the triad psychosis, mental deficiency and constitutional psychopathic inferiority or state, or whether a fourth diagnosis, no nervous or mental disease, is admissible.

A constitutional psychopath has been defined[19] as "one that does not possess and display the amount of kindliness, honesty, reliability, loyalty, independence, persistence, emotional control, and resistance to the development of psychotic episodes, average for his race and intelligence level; he need not be deficient in all these qualities, but his deviation from the normal is permanent and appears in his history as a developmental defect."

The following case histories are illustrative of the more commonly found characteristics:

Case 1.—*Prewar.*—Admittedly he was a frequent truant from school; finally he left when in grade 5 B, at the age of 16. He was subject to fits of temper. He worked as a laborer and factory helper, continuing only for short periods at successive jobs; e. g., three months, one month, one month.

Military.—He was inducted, April 2, 1918, and discharged without disability, April 2, 1919. He stated that he spent three months in a hospital after being gassed, Sept. 27, 1918, and that cough and nervousness had persisted since.

Postwar.—He worked for brief periods as a shipping clerk. He was violent and abusive to his sister and his mother, whom he called a prostitute. He was granted training with pay by the Federal Board for Vocational Reeducation; he insisted on frequent trials of different types of training, taking successively sign painting, electric apparatus manufacturing, electric wiring, pen making, mechanical drawing and agriculture. In every place he paid little attention to work, but harangued other trainees and occasionally abused bureau officials and employers; he was often late or absent without leave, generally obstinate in refusing to follow directions, and domineering and disagreeable to his fellow trainees, failing in the task at hand but always claiming that he could succeed at something more complicated. Transfers and reinstatements in training were finally stopped after he had been treated more than liberally, and he spent the next two months idling about the bureau office, trying to cajole or browbeat the authorities into granting him further funds, without making any attempt to secure employment. He was a prolific letter writer, and in a loquacious letter to a bureau chief, he called the teachers who had endured so much from him "contemptible curs" and scornfully described his medical treatment on the same page with his claim that he had been refused all treatment. Physiotherapy had been arranged for him, which he refused to take. When psychotherapy was attempted, he tried to argue the medical examiner out of every approach he made. He spent recklessly the ample government money received while in training, saved nothing, and was irregular in paying his board bill. He refused to make any contribution to the maintenance of his mother, who was in need. He liked to be melodramatic with the Red Cross and other social workers, whose reports emphasized his exaggerated sense of his own importance. He was arrested four times for disorderly conduct.

He was repeatedly examined as a psychotic suspect, but no mania, paranoid state or other psychosis was ever diagnosed in his case. Psychometrically he measured of superior intelligence, with intelligence quotient 119. Physically he never showed more than a mild bronchitis, which he exaggerated to the utmost.

Case 2.—*Prewar.*—In childhood, he was admittedly incorrigible at home; the school records showed him poor in studies and deportment, and difficult to discipline; he was bad tempered, and tried to strike the principal. He did not go beyond the eighth grade, though he claimed that he had finished high school at 15. He worked at odd jobs.

Military.—He enlisted, March 3, 1918, at the age of 16, which he gave as 18; he was discharged without disability, June 19, 1919, though he afterward claimed that he had had various sorts of "spells" after being "gassed" in France. Later he enlisted in the navy, from which he received a medical discharge for nervousness.

Postwar.—After his second discharge, he worked again at odd jobs, in a dance hall, driving a car for friends, etc. He went from place to place, living by his wits, and was hospitalized in different cities for vague and variable nervous complaints. He sought sympathy from one prospective employer by declaring that he had only one lung, when in fact he did not even have bronchitis.

He worked only two months, and was dropped for his lazy attitude. He was granted training with pay by the federal board; he had trouble with the training officers on account of his irritability, lack of interest, and thoroughgoing unreliability; he started in mechanical dentistry, transferred to dentistry, and then went back to mechanical dentistry.

He married hastily, lived with his wife only two days, and took the episode as a joke. She returned to her parents in three weeks on account of his abandonment and abuse. Afterward he talked bombastically of what he would do to her if he found her.

On examination, he would pull himself away from the examiner and hold himself rigid instead of cooperating. At one time he attempted to malinger epilepsy. He had no physical disease; he showed onychophagia, but little else objectively. He failed to keep his appointments for treatment.

When asked his age, he replied: "I've lied so much about my age, I don't know what it is." When asked why he left one city on one occasion, he gave three different conflicting reasons in the same conversation. His social service history was filled with notes on his habitual lying and trouble with every one.

Case 3.—*Prewar.*—He had two years' high school education, followed by an evening commercial and a correspondence course. In view of his mental capacity and training, his spelling was poor. He worked as a traveling salesman. He was always restless and fidgety.

---

[18] Sands, I. J.: The Psychiatric Clinic in the General Hospital, J. A. M. A. **85**: 723 (Sept. 5) 1925.

[19] Anonymous.

Military.—He enlisted, Oct. 7, 1917, at the age of 25, and was discharged without disability, Nov. 23, 1918. He did not go overseas and was not exposed to any stress other than an operation for a sacrococcygeal cyst.

Postwar.—He worked for a short time, and then claimed nervousness on account of the cyst, which was inconsequential; he demanded and obtained hospitalization, during which it was again operated on.

He was granted federal board training with pay, which he retained for three years, while constantly applying for transfer from one subject to another; he was given sign painting, photography, and four varieties of salesmanship training. Eventually his lack of cooperation and absences without leave caused the termination of his training; he then spent a long time trying to be reinstated, instead of trying to work.

On examination, he claimed severe incapacitating illness, physical and nervous, demanding treatment and more training, and in almost the same breath claimed that he was making more money in his prewar work than he would receive in training. He evaded direct questions, dilated glibly on diagnoses, and took issue with the examiner on the technical features of the neurologic examination. Most of his complaints were belied by his manner of relating them. He appeared to be in the best state of health when he complained most volubly. He took no interest in improvement, repeatedly missing his appointments for treatment.

CONCLUSIONS

1. Five hundred diagnoses of constitutional psychopathic inferiority and constitutional psychopathic states, by thirty-three neuropsychiatrists, have been based on a number of accepted symptoms and symptom-complexes of these conditions, emotional instability being the most frequent.
2. The diagnosing of constitutional psychopathic state, emotional instability, is unsound unless this instability is definitely shown to be a fundamental attribute, not one acquired in later life.
3. In the present state of medicopsychologic knowledge, constitutional psychopathic inferiority or state should be considered a symptomatic, not a pathologic, diagnosis.
4. Criminalism should be omitted from the list of constitutional psychopathic states, since crime and responsibility are problems still too disputed and too extensive for its boundaries.

230 Central Park South.

ABSTRACT OF DISCUSSION

Dr. William House, Portland, Ore.: There is urgent need for a more acceptable concept of the term "constitutional psychopathic inferiority," and the analysis presented by Dr. Huddleson is helpful to that end. But it deals only with males whose reactions have been influenced by military service and who, in many instances, are capitalizing natural weaknesses not at all the results of that service, to lessen the burdens of existence. The reactions of those to whom such opportunities are not open will produce many symptoms not on his list, as those occurring in women and peculiar to their sex, the nature of some of which may readily be inferred. Constitutional psychopathic inferiority may manifest itself long before military age, or, though it has been present from birth, it may escape detection until long past military age, with results which, naturally, Dr. Huddleson has not mentioned. One of the most important symptoms that first calls it to attention is lack of adaptability to changing conditions and environment. To comment on some of the symptoms discussed, metatopomania is perhaps no more frequent than its antithesis, and those who live a lifetime in one place, remote from the conveniences and comforts of modern civilization, often do so because inferiority has made it impossible for them to make any struggle for existence other than that of work, often poorly done, which requires little planning. Likewise, polypraxia is probably no more frequent than the reverse, that is, inability to escape from the rut of what, by way of contrast, might be called monopraxia; and a lifelong pursuit of a single kind of work that is unprofitable and uncongenial is often the result of lack of resourcefulness and adaptability, which makes change difficult or impossible. Even criminality as a possible symptom of inferiority has its opposite in those whose lives are rendered futile by overconscientiousness. My concept of a psychopathic inferior individual is that of one who is fundamentally, congenitally and usually inherently defective, from structural, as opposed to pathologic, incompetence, either in the quality of the materials of which he is made or in the faulty assemblage of his mechanisms, but whose defects do not reach the degree of feeblemindedness; who gets along fairly well if kept strictly within his limitations, but falls below the average in ability to reason and apply the results of reasoning pragmatically; who, as a rule, exhibits many stigmas, and who readily develops a psychopathy when subjected to unaccustomed strain. He is, in short, a kind of human "flivver," possessing many of the virtues of a "flivver," but developing its erraticisms when least expected and often at the most inopportune times.

Dr. Sidney I. Schwab, St. Louis: I should like to ask Dr. Huddleson just what advantage there is in attempting to divide a material of that sort in so complex a manner. There are so many terms of doubtful meaning in his classification and some of the words are so difficult to understand and are susceptible of so many different interpretations that a confused idea may well result. A great many of the subdivisions and classifications are apt to be interpreted from a purely personal point of view; that is, the reader of the paper may know just what the terms signify, but the reader of or listener to the paper may have but little conception of their meaning. A minute classification does not necessarily add clearness to the conception of the subject. My criticism, simply stated, is that an intricate system of classification does not of itself throw any additional light on the meaning, interpretation or understanding of the subject.

Dr. Theodore Diller, Pittsburgh: I endorse Dr. Schwab's criticisms. There is a great danger in complexity. We ought to be careful about being overcomplex. We are made fun of, in a way, by our colleagues about our overtechnicality, and there is great danger in all of these things. I doubt very much the value of such an elaborate classification as has been attempted by Dr. Huddleson.

Dr. James H. Huddleson, New York: In referring to Dr. House's criticism, we can say that there are a number of parallel circumstances that apply to military and industrial problems. Of course, the criticism that this paper does not include any observations on the female sex is perfectly correct; also, that it applies to more or less limited age groups among men. That criticism is perfectly justified as well. I agree in every way with Dr. House that stigmas should be mentioned oftener; but this paper is a compilation of the work of thirty-three different neuropsychiatrists, and in the examinations that were made by these men the presence of stigmas was not emphasized; it was rather minimized. Regarding what Dr. Schwab has said, that not much is added to the sum of human knowledge by the work that has been done, he is perfectly correct.

Dr. Schwab: I did not say that at all. I was referring to my own incapacity to understand.

Dr. Huddleson: The only feeling I had in regard to this was that it was a correlation of the findings of different neurologists, and it might be possible to arrive at an average of the different conceptions that were held by these different men. They all were working on the same problem, but from different points of view, as Dr. Schwab has said. It is not intended in any way to be the last word, and it is quite possible that in some ways the terms used are a little more complex than the trait that they are intended to depict. The interpretation of the findings for a given case was the interpretation not of the compiler but rather that of the examiner who made that particular examination, with the idea in the compilation of averaging all these interpretations as far as possible Metatopomania simply means moving from place to place.

CLINICAL TESTS OF THE OVARIAN FOLLICULAR HORMONE *

J. P. PRATT, M.D.
DETROIT

AND

EDGAR ALLEN, Ph D
Professor of Anatomy, University of Missouri School of Medicine
COLUMBIA, MO

The frequent complaints of disturbed menstruation brought to the clinician serve as a constant stimulus to him to seek the fundamental cause for these disturbances In order to evaluate properly the disturbances of menstruation one must first explain the normal periodic changes that occur in the genital organs Up to the present time, explanations of these changes have lacked an extensive foundation of an experimental nature There are, however, many observers keenly interested in the subject in both the laboratory and the clinic From these sources valuable contributions are frequently appearing which bring nearer the final solution of the problem.

That the normal menstrual cycle is largely dependent on ovarian function is well established The ovary cannot be considered alone, however, for evidences of interrelation of the ductless glands are ever present The improved understanding of one gland aids the interpretation of the functions of others The vastness of the work has been well expressed by Dr. Abel [1] "Never before were there so many investigators, chemists, biologists, pathologists and clinicians engaged in one phase or another of this enormous subject. Already the usual output of special articles in this field numbers 3,000 per annum" For obvious reasons, therefore, no attempt will be made to review all the literature.

The isolation of chemically pure substances that represent the active principles of other ductless glands, such as epinephrine, thyroxin, pituitary extract and insulin, stimulates the hope that the ovary will also yield a similar product. The various extracts of the ovary prepared commercially are useful chiefly for their psychic effects. Experimentally, there is little evidence that watery or dried extracts of the ovary are potent The results obtained from extracts made with lipoid solvents have, however, been proved effective in laboratory animals.

Iscovesco,[2] in 1912, used organic solvents to extract a hormone from the ovary which caused a certain amount of growth in the uterus of the rabbit. In 1914, Okintschutz described the arrest of uterine degeneration after double ovariectomy by injections of ovarian extracts. In 1915, Herrmann [4] and Frank and Rosenbloom [5] reported the extraction of a hormone from the placenta and from corpora lutea of domestic animals. They also used growth in the uterus of test rabbits as a criterion of activity. Great emphasis was placed by these [6] and others of the earlier investigators of this problem on the corpus luteum as the principal ovarian source of this hormone, although consistently positive results were not always obtained.[5] In 1922, Frank [7] announced in a single paragraph in a critical review that injections of fresh liquor folliculi produced uterine growth in young rabbits in which the ovaries were still intact (four cases). This was published five years after the work was done. Due credit should be given Frank for these preliminary experiments.

In 1923, Allen and Doisy [8] published a preliminary report of results of injections of fresh liquor folliculi and extracts of liquor folliculi into rats and mice. In these experiments,[9] it was shown that injections of the follicular hormone caused growth in the vagina as well as in the uterus of these animals. A degree of growth equivalent to the maximum occurring in the normal animal was obtained by injections. This growth in the vaginal walls replaced a maximum reaction equal to that in a normal animal under the influence of the ovaries for the partial reaction of earlier workers. This reaction could be easily followed by several observations on the living animal, while formerly criteria of activity of extracts depended on a single observation at necropsy. Furthermore, these tests can be rigidly controlled. The clear cut nature of the end-point of the rat and mouse tests made possible the definition of a quantitative unit for the standardization of extracts and measurement of the amount of active material present in different tissues.[10] A rat unit may be defined as the least amount of lipoid extract required to produce this reaction in the spayed adult rat It was further demonstrated [9] that normal mating reactions occurred in these spayed test animals as a result of injections of the follicular hormone These results were interpreted as a complete substitution with extracts for ovarian endocrine function in nonpregnant rats and mice. In these animals, at least, no endocrine secretion from the corpus luteum seemed necessary

In extending this work, positive tests have been secured with extracts of isolated follicles or follicular contents from hen,[11] cow, pig, sheep and human ovaries. Only negative results were obtained from extracts of comparatively large amounts of corpora lutea of estrus and pregnancy from pigs and cows.[12] For these reasons, the active substance was called the ovarian follicular hormone

Much recent work on this problem has been reported by Brouha and Simonnet,[13] Courrier,[14] Dixon,[15] Frank

and Gustavson and co-authors,[16] Hisaw,[17] Murphy and co-authors,[18] Papanicolaou,[19] Allen, Dupré and Hartman,[20] Ralls, Jordan and Doisy,[21] Shaw,[22] *Seckinger,[23] Laqueur and co-authors,[24]* Steinach and co-authors,[25] and Zondek and co-authors.[26] These investigations are extending our knowledge of the subject so rapidly that no adequate attempt can be made in this paper to review them.

In quantitative measurements of active substance in human genital tissues,[27] a relatively large amount of hormone has been extracted from the placenta at several different periods of gestation. The contents of large follicles and corpora lutea have been removed from the ovary at operation and tested quantitatively as a beginning toward the establishment of the range of hormone secretion during the menstrual cycle. More than 7 rat units of hormone per cubic centimeter were obtained *from follicular contents, as compared with more than* 3.7 and more than 2 rat units per cubic centimeter from groups of several corpora excised at operations during the third and fourth weeks of the menstrual cycle, respectively. The finding of considerable amounts of the follicular hormone in human corpora is in decided contrast to our results from tests of corpora of cows and pigs.[28] This difference in hormone content of corpora is considered a probable causal factor in some of the differences between the menstrual cycle in primates and the estrual cycle in lower animals.[29]

The most striking difference is the occurrence of menstruation in primates, man and monkeys, for in no other animal is such a function found. The outstanding event of the estrous cycle in most mammals other than primates occurs at or near ovulation, while menstruation occurs midway between ovulations. The mating instinct of mammals at times of rut or heat is very intense, and it is sharply limited to a period of a few hours or days. In primates there seems to be no particular relationship between *this instinct and ovulation.* The changes in the external genitalia accompanying rut or heat are very striking in many animals, while in woman these changes are minimal during the varying phases of the cycle. These differences make a direct application of results from laboratory animals to human patients difficult. Therefore, an investigation was begun of the effects of injections of ovarian and placental extracts into monkeys.[30] A typical menstrual cycle occurs in monkeys.[31] In addition to the usual human menstrual phenomena there is marked reddening and swelling of the cutaneous regions surrounding the external genitalia.

A PRELIMINARY NOTE ON EXPERIMENTAL WORK ON MONKEYS

1. Two unfertilized ova[32] have been recovered from the fallopian tubes of two monkeys on the tenth and fourteenth days following the first appearance of the previous menses. Together with an unfertilized tubal ovum and a degenerating uterine ovum recovered by Corner, these quite definitely establish the time of ovulation, if it does occur during the cycle in question, in the latter half of the second week of the menstrual cycle. There is ample evidence that ovulation does not occur during many apparently normal cycles.

2. Removal of both ovaries or injury to large follicles[33] immediately after, or toward the end of, the follicular phase of the cycle was followed by apparently typical menstrual bleeding. These operative menses began on the fourth to the sixth day following the removal of ovarian hormonal influence. Reddening and swelling of the vulva and surrounding regions disappeared after double ovariectomy.

3. Thirteen series of injections of ovarian and placental extracts have been completed in five spayed monkeys.[34] From 64 to 190 rat units of hormone have been injected over intervals varying from nine to twenty days, two or three injections being given daily to insure nearly continuous action of the extracts. Typical reddening and swelling of the vulva and surrounding regions and reddening of the nipples have been induced. *Disappearance of leukocytes and growth of the vaginal* epithelium to the point of cornification have been indicated by smears of vaginal contents. Considerable growth has been induced in the uterus. In seven of ten series, bleeding followed discontinuance of injections in from three to seven days. The duration of these experimental menses varied from one to six days. The flow was scant but characteristic. No bleeding occurred during the period of injections, and none followed three series in an animal from which the uterus had been removed.

Histologic studies of the genital tissues involved and physiologic studies of contractions of the tubes are under way to check these results further.

From these experiments, combined with earlier ones in lower mammals, we are inclined to conclude tentatively as a basis for clinical tests that:

1. The ovarian follicular hormone starts the periodic growth processes in the female genital tract.
2. In case ovulation occurs, the corpus luteum in woman,[35] and perhaps in other primates, may continue this anabolic endocrine influence, which probably decreases as the next menses approach.
3. Menstruation seems to be partly due to the temporary absence of this secretion after it has been acting for a certain time.
4. But since ovulation followed by corpus luteum formation often does not occur, a specific secretion of the corpus luteum is not a necessary causal factor in the menstrual cycle. That the corpus luteum may possibly have a regulatory influence is not questioned.
5. This substance or a very similar one is probably secreted by, or stored in, the placenta. Its continuous availability throughout the gestation period would account for the absence of menstruation during pregnancy.

CLINICAL TESTS

Material Injected.—The ovarian follicular hormone injected into patients represented two kinds of preparations. Both were begun by extracting follicular fluid with lipoid solvents. One was a watery emulsion,[36] the other an oil solution of residues. The potency of these extracts was tested before their clinical use by injections into spayed rats. The strength varied from about 0.5 to 3.7 rat units per cubic centimeter. This material was injected subcutaneously in the deltoid region. No unpleasant reactions either local or general were experienced, with the exception of a transient burning sensation by watery emulsions at the site of the injection. The oil solution did not seem to call forth any local reactions, such as subcutaneous lumps.

In testing the effect of the follicular fluid in animals, the conditions necessary for satisfactory proof can be readily controlled. The animals selected can be of a suitable age, free from complicating disease, and the conditions of the experiment can be varied to suit the requirements. The difficulties are increased when these tests are applied to the human being. 1. There must be the cooperation of the patient.[37] 2. There must be no complicating disease. 3. The patient's build must be such that a satisfactory pelvic examination can be made without an anesthetic. 4. The conditions cannot be varied to suit the problem, but the material must be chosen from the rank and file of patients.

Although as indicated above, there are many differences between the menstrual cycle of primates and the estrous cycle of other animals, there is one thing common to all, and that is the periodic growth and regression of the uterus in response to stimulation from the ovaries. In primates this regression is accompanied by the menstrual flow, in other mammals it is not.

In order to test the action of the follicular hormone on the human cycle, suitable individuals have been selected from time to time. The experimental nature of the work has been carefully explained to them. This has secured their cooperation to the extent that several have made trips to the hospital from a considerable distance twice a day. Some patients have felt benefited to such an extent that they have returned to ask a continuation of the treatment. Others have noted no improvement and have discontinued treatment before satisfactory conclusions could be arrived at.

Since the main problem has been to substitute extracts for diminished or absent ovarian secretion, an attempt has been made to exclude complicating diseases or disturbances of the other ductless glands. Out of many cases that have been considered, the following groups have been chosen: 1. Artificial menopause. 2. Natural menopause. 3. Primary amenorrhea. 4. Scanty menstruation. 5. Immaturity.

Artificial Menopause.—The condition that most closely simulates the animal experiments is the artificial menopause following removal of ovaries with the uterus intact. The following case report typifies this group:

Mrs. I. D., aged 36, had had four pregnancies. The menstrual cycle was regular, twenty-eight days, until both ovaries were removed one year previous to the injections. There had been no menstruation since the operation. There had been some nervousness and recurrent hot flashes. She also complained of painful breasts. A series of two injections a day for twenty-three days was given. Each dose represented 0.5 rat unit. After the third day the patient noted some feelings of pressure in the pelvis. This feeling of pressure gradually increased throughout the series of injections. There was also a very evident change in the circulation of the uterus, as on inspection before the injections were begun the cervix was small, atrophic and pale, but as the injections proceeded the color of the cervix changed as the circulation improved, becoming red to purplish. Also on inspection the size of the cervix was noted to increase. With bimanual palpation the fundus was found to enlarge until the end of the injections, at which time it seemed nearly twice the size that it was before the injections were begun. As the fundus enlarged the patient stated that she felt the same symptoms that she formerly experienced as menstruation was approaching, a sense of pressure particularly noticeable on the left side and also in the bladder. The objective symptoms of enlargement were unquestionable. It is quite probable that one should discount some of the subjective symptoms, as the patient was somewhat nervous and was probably unduly impressed by the sensation of returning menstruation. She even mentioned that on the seventeenth day of injections she noted certain nervousness and forgetfulness which almost amounted to mental confusion, which she then recalled had been present with each menstruation for the four or five years preceding the operation that brought about the menopause. Also she noted an increased tenderness in the mammary glands, which often occurred previously with former menstruations.

The consistency of the uterus when the injections were begun was very firm. As the enlargement proceeded, there was some softening. At no time was there any flow. The patient was very slight and bimanual examination easily accomplished, so that we feel an estimate of the change in the size of the uterus is quite fair even though no absolute measurements could be made. This increase in the size of the uterus was checked by disinterested observers.

Five series of injections in women with artificial menopause have been made. All these patients have been in the third decade of life. The interval between the removal of the ovaries and the injection has varied from two months to two years. In each case, examination of the patient before the injection has shown atrophy or involution of the uterus which follows loss of the ovaries. The dosage used has been from 0.5 to 3 rat units morning and evening daily for two or three weeks. The results obtained in this group have been fairly uniform:

[35] Allen, Pratt and Doisy (footnote 27). Footnote 28.

[36] This material was supplied by Parke, Davis & Company.

[37] In the summer of 1923 preliminary clinical tests of solutions of hormone in oil were begun by the junior author in collaboration with Dr. O. L. Newell of the gynecologic clinic at Washington University School of Medicine. Injections were begun in seven different patients. Only two of the seven were willing to continue treatment to the point at which results seemed worth while. Daily injections over a period of two weeks in summer time become tiresome, especially when the malady is not fatal. Because of the subjective nature of much of the evidence these preliminary results were not published. Later more thorough work has supplied better evidence establishing most of the results of these preliminary tests.

Objective Criteria Noted: A few days after the injections were begun, an increase in the size of the uterus was noted. This growth continued for several days. During the latter days of the injections over the period of from two to three weeks, the rapidity of the growth was less noticeable. As soon as the injections were stopped the uterus diminished in size, returning in a few days to the size noted before the injections were begun. At the height of growth there was some change of color in the cervix seen through the vaginal speculum, the cervix showing a definite increase in the amount of circulation. On two different occasions following the cessation of the injections, a very small streak of blood appeared. Because of the momentary duration of this, we hesitate to call it menstruation. The growth was determined by bimanual pelvic examinations.

Subjective Criteria: The patients noted also the increase in the size of the uterus because they all mentioned the feeling of pressure and heaviness in the pelvis which they had formerly experienced, especially at the time of menstruation. Many other subjective symptoms were noted, but these must be greatly discounted on account of the patient's desire to have the symptoms reproduced.

Natural Menopause.—The outstanding features associated with a natural menopause are the "hot flashes" and nervousness. Since these are subjective symptoms, they do not offer an especially good test for the effects of the follicular hormone. However, it seemed advisable to try a certain number of cases of this sort for the sake of comparison with the other types of ovarian disturbance. Several patients of this group have been treated with injections. All of them have reported improvement in both the nervousness and the hot flashes. The following case report typifies this group:

Mrs. K. D., aged 47, had had symptoms of hot flashes, nervousness, and pains in the breast for somewhat more than a year, the hot flashes occurring about five in twenty-four hours. After five daily injections of follicular fluid containing about 0.5 rat unit each, the patient noticed a diminution in intensity of the hot flashes and also some improvement in the painful breasts. With the next five doses there was a distinct decrease in the intensity and in the number of the hot flashes, and there was also experienced an improvement in the condition of the breasts and general nervousness. At this time daily doses were given over a period of a week which had no potency, this fact being discovered later. The patient complained during this week that her old symptoms had returned. As soon as the discovery was made that the injections were impotent, the change was made to a known solution containing 0.5 rat unit for each injection. Within a few days the hot flashes disappeared and the patient's general condition improved. With the cessation of treatments at the end of three weeks, the hot flashes gradually reappeared; but in a period of four months they have not returned to the same frequency or intensity that they were before the injections were begun.

It must be remembered in interpretation of the influence of the hormone in cases of natural menopause that all the symptoms considered are subjective. In addition to the case cited above, several other patients were given these follicular injections. It was found that it did not require a very high dosage to modify the symptoms in this group of patients.

Primary Amenorrhea.—The third group of persons in whom the injections were tried may be spoken of as having a primary amenorrhea, that is, they have passed the age of 20 without yet having menstruated. While it is impossible to separate the influence of various ductless glands, as far as could be determined, we have excluded those that show a definite hypofunction of either the thyroid or the pituitary. The basal metabolism has been normal. These subjects have all been hard to check on account of the lack of development of the pelvic organs, making an accurate pelvic examination somewhat difficult. In this group of cases there have been five series of injections varying from two weeks to two months, once a day to three times a day. The total number of rat units varied from 15 to 90. In this group there has been a definite but slight amount of growth with the larger doses, but no sign of menstruation in any case. No subjective symptoms were noted.

Scanty Menstruation.—In this group there have been six series of injections. The patients chosen have been in the second or third decade. In all of them the menstruation had been irregular either in interval or in amount since its onset. One of these cases is of unusual interest in that two years previous to the present study she had been given thyroid extract by mouth with resulting increased frequency of menstruation, but in very scant amount. The following case typifies this group:

Miss A. C., aged 31, started to menstruate at the age of 13. She was irregular from the start. The average interval was two months, and the duration never over three days. This continued until the age of 18, at which time the menstrual periods became more irregular with gradually diminishing amount at each flow. At the age of 27 the average flow was about three or four times a year. At this time the patient was given thyroid extract by mouth over a period of many weeks. During this therapy she came to menstruate every month for a period of six months, but with no particular increase in the amount. The thyroid extract was discontinued. The menstruation again became irregular. The year preceding the present series of injections, the patient had menstruated twice. She was given one injection a day of 1 rat unit for five days. Following this she flowed about twice as much as at the previous period some eight months before. The injections were begun again about twelve days after the menstrual flow was established. Following injections of the fluid for eleven days, the flow was reestablished. There was a slight increase in amount over the one previous. The injections were then discontinued for another twelve days and begun again and at the same interval the menstrual flow appeared. This flow was, as the patient stated, "the most like what I have heard other people say was a normal menstruation—more than I have ever menstruated at one time in my life."

This patient is of especial interest on account of the menstruation having been apparently influenced by thyroid extract and at a later date by the follicular hormone, showing the possibilities of interrelation of the ductless glands. The conditions found in this patient do not meet ideal experimental conditions in that ovaries of some sort are still present in the subject. However, there seems to be a very direct cause and effect. Further study will be necessary in this particular case to check the influence the hormone may exert.

Immaturity.—In the animal experiments, one of the striking tests has been the hastening of sexual maturity so that the estrous cycle becomes established much earlier in injected animals than in controls. There has been no justification in human beings to reproduce this test in normal persons.

SUMMARY

Injections of ovarian follicular hormone into primates, monkeys and human beings, from which ovaries

have been previously removed, produce growth in the uterus.

Removal of the ovarian follicular hormone by oophorectomy or cessation of injections brings on menstruation in monkeys.

Uterine growth and accompanying subjective symptoms similar to those previously experienced at time of menstruation have resulted from injections into patients whose ovaries have been previously removed. No bleeding approximating that of normal menstruation has as yet appeared in women.

In one case of scanty and irregular menses in which the ovaries were still intact, a definite increase in flow and regularity has resulted from injections of the hormone.

ABSTRACT OF DISCUSSION

Dr. Arthur H. Curtis, Chicago: I should like to know the technic employed in the preparation of the hormone.

Dr M. I. Smith, Pearl River, N. Y.: I wish to ask the speaker whether larger doses of the hormone might not have been more effective in his clinical cases. As I understand it, from a half to one unit is a very small dose and is hardly sufficient to bring about results in the experimental animal. It seems to me that the human being ought to get in proportion a larger dose.

Dr. J. P. Pratt, Detroit: The preparation of the ovarian follicular hormone has been given in detail elsewhere. For this reason details have been omitted in this paper. The hormone may be extracted from the ovarian follicles, human corpus luteum or placenta. It has been sufficiently purified for injection into human beings without the slightest reaction. Some patients have had a series of at least twenty-four injections in one location without any reaction. The dosage used has been small. It is hoped that the hormone will be later available for clinical use. It is desirable, for this reason, to determine the minimum dosage necessary as the preparation is still an expensive process. There has been some difficulty, up to the present time, in concentrating the hormone so that larger doses can be given without necessitating the injection of a large amount of fluid. So far only doses of 1 cc. of fluid have been used. Now that the concentration has been increased, the reactions are more prompt and more striking. It is quite possible that other results will appear with the injection of larger doses.

Tuberculin Prepared from Nonprotein Substrates.—It has been shown for the first time that small amounts of tuberculin fractions prepared from protein-free synthetic substrates are capable of sensitizing normal, nontuberculous guinea-pigs. In these animals, typical skin reactions can be elicited subsequently by intracutaneous injection of minute amounts of homologous as well as heterologous fractions and of unfractionated tuberculin from which such fractions have been prepared. Clinical trial of these fractions in juvenile patients has demonstrated for the first time that the substances have diagnostic value. Positive skin tests were perfectly correlated with positive clinical and laboratory findings of tuberculous infection. Such was not the case for ordinary old tuberculin in more than 20 per cent of young patients in a group of 150 who were studied routinely. In a number of instances the observations suggested that the reactions might be correlated with the degree of activity or with arrested tuberculous infection. These studies point to a method which makes an accurately standardized tuberculin available for routine clinical work. It is believed that the active principle of tuberculin can best be isolated by this or by a similar method. The observations on sensitization suggest that these may be applied to studies of immunity, and by extension, to therapeutic studies in the experimental animal. Such work, now in its third year of progress, will be reported in the future.—Eberson, Frederick: *Proc. Soc. Exper. Biol & Med.* **23**:511 (March) 1926.

PERIARTERIAL SYMPATHECTOMY *

R. W. McNEALY, M.D.
CHICAGO

[Editorial Note.—This paper, together with the paper by Drs. Cutler and Fine, which follows it, concludes the symposium on "Sympathectomy." In our last issue we published the three papers by Drs. Forbes and Cobb, Dr. Ranson, and Drs. Davis and Kanavel.]

Periarterial sympathectomy has been widely practiced during the last few years. Dealing as it does with a surgical attack on that enigmatic portion of our anatomy the sympathetic or autonomic nervous system, it has had the stimulating effect so commonly generated by research activities in comparatively unknown fields. The application of periarterial sympathectomy, or periarterial histonectomy, as Schilf [1] prefers to designate the procedure, as surgical therapy has evoked many pertinent questions as to the correctness of the physiologic hypothesis on which it is founded.

The first person to perform periarterial sympathectomy was Jaboulay,[2] who in 1889 removed the periarterial tissues from the femoral artery for the cure of certain perforating ulcers of the foot. The operation lapsed into obscurity until 1913, when Leriche [3] published an article on the removal and sectioning of the perivascular nerves in certain painful syndromes of arterial origin and in some trophic disturbances. Since this first paper, he has contributed many articles reporting his results with this operation in the treatment of various disorders of supposedly neurovascular origin.

In 1921, Leriche [4] described the effects of the operation, reviewed his observations and researches, and reported the results in sixty-four cases in which operation had been performed. This seemed to fire the imagination of surgeons everywhere, with the result that one now finds surgeons performing the operation for the most bizarre group of vascular disturbances. Leriche at various times has suggested its applicability in the treatment of Raynaud's disease, erythromelalgia, causalgia, trophedema, trophic ulcers, painful amputation stumps, ischemic sequelae, varicose ulcers, varicose eczema, intermittent claudication, thrombo-angiitis obliterans and disorders of the Babinski-Froment type. Recently there has been added to this somewhat related group such conditions as ununited fractures,[5] acute infections of the extremities,[6] tuberculous lesions of bone,[7] leprosy,[8] acute osteomyelitis [9] and pelvic disturbances in the female.[10] Anatomically, the field extends over practically every approachable vessel where denudation is practiced for the relief of local or neighboring pathologic conditions.

Publications dealing with the anatomy and physiology, case reports and modifications of technic of the operation have been appearing in considerable number both here and abroad. These writers have varied so widely in their results and have expressed such divergent views relative to the procedure that one feels it may be timely to attempt a critical review in tabloid form of the field, that the results of this operation may be properly interpreted and evaluated.

It is quite essential to establish first what is known of the anatomy and physiology of the portion of the sympathetic nervous system related to this operation. Further, it is hoped that this knowledge may serve to explain the clinical phenomena that follow the application of periarterial sympathectomy to peripheral vessels.

The operation was originally designed principally for an attack on those sympathetic dysfunctions of the vasomotor system which showed a predominance of vasoconstrictor action. Later the field of application was broadened to include conditions that might be benefited by active hyperemia which it was hoped could be brought about by a diminution in the normal vasoconstrictor tonus or by stimulation of the vasodilator elements.

The technic of the operation as practiced by most men consists in the isolation of a peripheral artery over a distance of from 8 to 10 cm. The vascular sheath or adventitia is divided longitudinally, and is then circumferentially dissected to effect a complete adventitial denudation of this sector of the vessel.

Following the stripping of the periarterial sheath there occur the following reactions, which appear quite constant and which most observers have been able to demonstrate to a greater or lesser degree, depending on the condition of the vessel and the manner and completeness of the operation: At the site of vascular denudation there occurs a primary contraction, which may reduce the vessel to one-third or even one-fourth its normal size. The pulse may disappear, but there is usually no interruption of the circulation. Following this initial contraction, in from three to fifteen hours there occurs a dilatation of the artery and a hyperemic condition of the extremity, with an increase of from 2 to 3 degrees of temperature, a feeling of warmth in the extremity, an increase in blood pressure, and dilatation of the capillary loops. This period of hyperemia lasts from a few days to several weeks.

While Leriche laid great stress on the completeness of the perivascular denudation over a considerable length of the vessel, other men have reported quite similar reactions following modifications of his technic. Novak [11] secured results from merely laying open the sheath of the vessel and freeing any adhesions in its circumference. Ahrens [12] has recently advised a blunt circumferential loosening of the adventitia for a distance of 1 or 1.5 cm. The sheath is left attached at both ends. This procedure he terms "sympathicolysis." Handley [13] has suggested injection of alcohol at points equally distant on the circumference of the vessel. He states that with the exception of the primary contraction locally of the vessel all other reactions are similar to neurectomy.

The reactions that are found to occur have been explained by Leriche, Hohlbaum,[14] Kappis,[15] Brüning [16] and others, as follows: The primary contraction at the site of operation has been explained as due to the excitation by trauma of the vasoconstrictor fibers at the site of operation. The secondary phenomena have been explained as being due to the interruption of the paths of the vasomotor fibers which were thought to pass from their origins in the dorsolumbar outflow of the ganglionated cord principally as a network in continuity along the vessels of the extremity. This interruption of the postganglionic fibers was meant to remove the preponderance of vasoconstrictor tonus. It was also believed that any long sensory paths which might reflexly influence the tonus of the vessels or which might in themselves carry painful sensations could likewise be interrupted.

While we may agree that the primary contraction and secondary phenomena occur in a more or less pronounced form in the majority of. cases, there still remain many incongruities in the explanation that they result essentially from interruption of long vasomotor tracts supplying the peripheral vessels. It is agreed that these phenomena are frequently transient, and this evanescence would speak very strongly against the basis of the reactions depending on any decided anatomic interruption of vasomotor nerve paths. Further, experimental investigation shows that the arrangement of vasomotor nerves to the blood vessels is in a segmental manner and cannot be interrupted except locally by the operation as now performed.

The classic experiment of Claude Bernard [17] first suggested the segmental distribution of vasomotor nerves. Recently Kramer and Todd [18] have shown that the vessels of the upper extremity receive their sympathetic fibers in a segmental distribution from special nerve trunks. The nerve twigs are distributed from the nerve trunks to the vessels at intervals, the intervals growing shorter as the more distal portions of the limb are reached. This distribution to the vessels corresponds pretty closely with the distribution of nerves to the skin and musculature of the same area.

Potts [19] investigated the distribution of the nerve supply to the arteries of the lower extremities. He also found a segmental distribution of nerves to the vessels similar to the findings in the upper extremity. This segmental distribution through peripheral nerves is corroborated by many experiments conducted along the lines of physiologic investigation.

Langley [20] showed that the normal response of the vasomotor nerves to stimulation is a vasoconstriction in the area supplied by the nerve. He also showed that stimulation of the lumbar sympathetics causes a vasoconstriction that is abolished when the peripheral nerves are cut.

Before further experiments dealing with the physiology of vasomotor activity are discussed, we may find it expedient to quote from Bayliss [21] a survey of those factors which control the normal state of blood vessel tonus. He states that the tonus is due to the natural property of smooth muscle to be in a state of tonus and to the continuous vasoconstrictor impulses sent out by the tonic excitation of the vasocontrictor center. Other factors are the contractions set up by epinephrine when have been previously removed, produce growth in the uterus.

Removal of the ovarian follicular hormone by oophorectomy or cessation of injections brings on menstruation in monkeys.

Uterine growth and accompanying subjective symptoms similar to those previously experienced at time of menstruation have resulted from injections into patients whose ovaries have been previously removed. No bleeding approximating that of normal menstruation has as yet appeared in women.

In one case of scanty and irregular menses in which the ovaries were still intact, a definite increase in flow and regularity has resulted from injections of the hormone.

ABSTRACT OF DISCUSSION

Dr. Arthur H. Curtis, Chicago: I should like to know the technic employed in the preparation of the hormone.

Dr. M. I. Smith, Pearl River, N. Y.: I wish to ask the speaker whether larger doses of the hormone might not have been more effective in his clinical cases. As I understand it, from a half to one unit is a very small dose and is hardly sufficient to bring about results in the experimental animal. It seems to me that the human being ought to get in proportion a larger dose.

Dr. J. P. Pratt, Detroit: The preparation of the ovarian follicular hormone has been given in detail elsewhere. For this reason details have been omitted in this paper. The hormone may be extracted from the ovarian follicles, human corpus luteum or placenta. It has been sufficiently purified for injection into human beings without the slightest reaction. Some patients have had a series of at least twenty-four injections in one location without any reaction. The dosage used has been small. It is hoped that the hormone will be later available for clinical use. It is desirable, for this reason, to determine the minimum dosage necessary as the preparation is still an expensive process. There has been some difficulty, up to the present time, in concentrating the hormone so that larger doses can be given without necessitating the injection of a large amount of fluid. So far only doses of 1 cc. of fluid have been used. Now that the concentration has been increased, the reactions are more prompt and more striking. It is quite possible that other results will appear with the injection of larger doses.

Tuberculin Prepared from Nonprotein Substrates.—It has been shown for the first time that small amounts of tuberculin fractions prepared from protein-free synthetic substrates are capable of sensitizing normal, nontuberculous guinea-pigs. In these animals, typical skin reactions can be elicited subsequently by intracutaneous injection of minute amounts of homologous as well as heterologous fractions and of unfractionated tuberculin from which such fractions have been prepared. Clinical trial of these fractions in juvenile patients has demonstrated for the first time that the substances have diagnostic value. Positive skin tests were perfectly correlated with positive clinical and laboratory findings of tuberculous infection. Such was not the case for ordinary old tuberculin in more than 20 per cent of young patients in a group of 150 who were studied routinely. In a number of instances the observations suggested that the reactions might be correlated with the degree of activity or with arrested tuberculous infection. These studies point to a method which makes an accurately standardized tuberculin available for routine clinical work. It is believed that the active principle of tuberculin can best be isolated by this or by a similar method. The observations on sensitization suggest that these may be applied to studies of immunity, and by extension, to therapeutic studies in the experimental animal. Such work, now in its third year of progress, will be reported in the future.—Eberson, Frederick: *Proc. Soc. Exper. Biol. & Med.* **23**:511 (March) 1926.

PERIARTERIAL SYMPATHECTOMY *

R. W. McNEALY, M.D.
CHICAGO

[Editorial Note.—This paper, together with the paper by Drs. Cutler and Fine, which follows it, concludes the symposium on "Sympathectomy." In our last issue we published the three papers by Drs. Forbes and Cobb, Dr. Ranson, and Drs. Davis and Kanavel.]

Periarterial sympathectomy has been widely practiced during the last few years. Dealing as it does with a surgical attack on that enigmatic portion of our anatomy the sympathetic or autonomic nervous system, it has had the stimulating effect so commonly generated by research activities in comparatively unknown fields. The application of periarterial sympathectomy, or periarterial histonectomy, as Schilf[1] prefers to designate the procedure, as surgical therapy has evoked many pertinent questions as to the correctness of the physiologic hypothesis on which it is founded.

The first person to perform periarterial sympathectomy was Jaboulay,[2] who in 1889 removed the periarterial tissues from the femoral artery for the cure of certain perforating ulcers of the foot. The operation lapsed into obscurity until 1913, when Leriche[3] published an article on the removal and sectioning of the perivascular nerves in certain painful syndromes of arterial origin and in some trophic disturbances. Since this first paper, he has contributed many articles reporting his results with this operation in the treatment of various disorders of supposedly neurovascular origin.

In 1921, Leriche[4] described the effects of the operation, reviewed his observations and researches, and reported the results in sixty-four cases in which operation had been performed. This seemed to fire the imagination of surgeons everywhere, with the result that one now finds surgeons performing the operation for the most bizarre group of vascular disturbances. Leriche at various times has suggested its applicability in the treatment of Raynaud's disease, erythromelalgia, causalgia, trophedema, trophic ulcers, painful amputation stumps, ischemic sequelae, varicose ulcers, varicose eczema, intermittent claudication, thrombo-angiitis obliterans and disorders of the Babinski-Froment type. Recently there has been added to this somewhat related group such conditions as ununited fractures,[5] acute infections of the extremities,[6] tuberculous lesions of bone,[7] leprosy,[8] acute osteomyelitis[9] and pelvic disturbances in the female.[10] Anatomically, the field extends over practically every approachable vessel where denudation is practiced for the relief of local or ner[illegible] conditions.

[illegible] with the anatomy and physiology, case reports and modifications of technic of the operation have been appearing in considerable number both here and abroad. These writers have varied so widely in their results and have expressed such divergent views relative to the procedure that one feels it may be timely to attempt a critical review in tabloid form of the field, that the results of this operation may be properly interpreted and evaluated.

It is quite essential to establish first what is known of the anatomy and physiology of the portion of the sympathetic nervous system related to this operation. Further, it is hoped that this knowledge may serve to explain the clinical phenomena that follow the application of periarterial sympathectomy to peripheral vessels.

The operation was originally designed principally for an attack on those sympathetic dysfunctions of the vasomotor system which showed a predominance of vasoconstrictor action. Later the field of application was broadened to include conditions that might be benefited by active hyperemia which it was hoped could be brought about by a diminution in the normal vasoconstrictor tonus or by stimulation of the vasodilator elements.

The technic of the operation as practiced by most men consists in the isolation of a peripheral artery over a distance of from 8 to 10 cm. The vascular sheath or adventitia is divided longitudinally, and is then circumferentially dissected to effect a complete adventitial denudation of this sector of the vessel.

Following the stripping of the periarterial sheath there occur the following reactions, which appear quite constant and which most observers have been able to demonstrate to a greater or lesser degree, depending on the condition of the vessel and the manner and completeness of the operation: At the site of vascular denudation there occurs a primary contraction, which may reduce the vessel to one-third or even one-fourth its normal size. The pulse may disappear, but there is usually no interruption of the circulation. Following this initial contraction, in from three to fifteen hours there occurs a dilatation of the artery and a hyperemic condition of the extremity, with an increase of from 2 to 3 degrees of temperature, a feeling of warmth in the extremity, an increase in blood pressure, and dilatation of the capillary loops. This period of hyperemia lasts from a few days to several weeks.

While Leriche laid great stress on the completeness of the perivascular denudation over a considerable length of the vessel, other men have reported quite similar reactions following modifications of his technic. Novak [11] secured results from merely laying open the sheath of the vessel and freeing any adhesions in its circumference. Ahrens [12] has recently advised a blunt circumferential loosening of the adventitia for a distance of 1 or 1.5 cm. The sheath is left attached at both ends. This procedure he terms "sympathicolysis." Handley [13] has suggested injection of alcohol at points equally distant on the circumference of the vessel. He states that with the exception of the primary contraction locally of the vessel all other reactions are similar to neurectomy.

The reactions that are found to occur have been explained by Leriche, Hohlbaum,[14] Kappis,[15] Brüning [16] and others, as follows: The primary contraction at the site of operation has been explained as due to the excitation by trauma of the vasoconstrictor fibers at the site of operation. The secondary phenomena have been explained as being due to the interruption of the paths of the vasomotor fibers which were thought to pass from their origins in the dorsolumbar outflow of the ganglionated cord principally as a network in continuity along the vessels of the extremity. This interruption of the postganglionic fibers was meant to remove the preponderance of vasoconstrictor tonus. It was also believed that any long sensory paths which might reflexly influence the tonus of the vessels or which might in themselves carry painful sensations could likewise be interrupted.

While we may agree that the primary contraction and secondary phenomena occur in a more or less pronounced form in the majority of. cases, there still remain many incongruities in the explanation that they result essentially from interruption of long vasomotor tracts supplying the peripheral vessels. It is agreed that these phenomena are frequently transient, and this evanescence would speak very strongly against the basis of the reactions depending on any decided anatomic interruption of vasomotor nerve paths. Further, experimental investigation shows that the arrangement of vasomotor nerves to the blood vessels is in a segmental manner and cannot be interrupted except locally by the operation as now performed.

The classic experiment of Claude Bernard [17] first suggested the segmental distribution of vasomotor nerves. Recently Kramer and Todd [18] have shown that the vessels of the upper extremity receive their sympathetic fibers in a segmental distribution from special nerve trunks. The nerve twigs are distributed from the nerve trunks to the vessels at intervals, the intervals growing shorter as the more distal portions of the limb are reached. This distribution to the vessels corresponds pretty closely with the distribution of nerves to the skin and musculature of the same area.

Potts [19] investigated the distribution of the nerve supply to the arteries of the lower extremities. He also found a segmental distribution of nerves to the vessels similar to the findings in the upper extremity. This segmental distribution through peripheral nerves is corroborated by many experiments conducted along the lines of physiologic investigation.

Langley [20] showed that the normal response of the vasomotor nerves to stimulation is a vasoconstriction in the area supplied by the nerve. He also showed that stimulation of the lumbar sympathetics causes a vasoconstriction that is abolished when the peripheral nerves are cut.

Before further experiments dealing with the physiology of vasomotor activity are discussed, we may find it expedient to quote from Bayliss [21] a survey of those factors which control the normal state of blood vessel tonus. He states that the tonus is due to the natural property of smooth muscle to be in a state of tonus and to the continuous vasoconstrictor impulses sent out by the tonic excitation of the vasocontrictor center. Other factors are the contractions set up by epinephrine when this substance is present in the blood; also possibly the contraction by which they respond to the natural stretching force of the blood pressure.

Of these several factors, we are especially concerned with the continuous vasoconstrictor impulse which is the variable by whose modified activity it was hoped the caliber of peripheral vessels could be influenced, the point of attack having been principally directed to the interruption of the efferent fibers, thereby removing the control of the vasoconstrictor center over the peripheral vessels. The futility of securing interruption of any considerable number of fibers by removal of a segment of vessel sheath has been shown by Milko,[22] Schilf [23] and others, who secured no change in the blood flow in the extremity of a dog when the sheath of the femoral artery was stimulated Wiedhopf [24] likewise found no plethysmographic changes in the foot of a dog following periarterial sympathectomy. Melzner [25] removed the perivascular sheath of the renal artery of a dog and found no histologic differences between the kidney that had been operated on and the kidney that had not Bowing [26] showed that vasomotor reflexes are maintained after sympathectomy but are abolished when the peripheral nerves are cut.

With the accumulation of evidence that the effects of this operation are not due to interruption of the efferent tracts, it is suggested by Bruning [27] that they are due to interruption of afferent tracts which are likewise supposed to travel in the periarterial sheaths of peripheral blood vessels Andre Thomas,[28] as early as 1917, suggested that deep sensations were transmitted in the nerves traveling in the vessel sheath This explanation seemed plausible and helped to explain the disappearance of pain which has been noted frequently in patients who have been operated on The experimental work of Friedrich [29] seemed to support this view, but the researches of Dennig,[30] who duplicated the work of Friedrich under better controlled conditions, demonstrates that no long vasodilator fibers nor long sensory paths travel in the adventitia of peripheral vessels Wiedhopf's [31] researches seem to support the work of Dennig.

Another explanation has been offered for the hyperemia that follows operations on an extremity It is fairly well known that stimulation of a sensory or mixed nerve produces a very decided vasomotor change in an extremity. In 1866, Loven [32] showed that stimulation of the great auricular nerve of a rabbit produces vasodilatation in the rabbit's ear. He also showed that stimulation of the anterior crural nerve of a dog produces local dilatation of blood vessels of the extremity, with vasoconstriction elsewhere and an increase in general blood pressure These experiments speak for active vasodilator nerves which receive their impulses as a reflex through the dorsal root sensory fibers, or it is possible that they may be antidromal in type, corresponding in many ways to the "axon reflex" described by Langley.

Lawen [33] stretched the sciatic and saphenous nerves in an elderly patient as a remedy for arteriosclerosis and hypothermia of the foot. He produced a hyperthermia with some motor paralysis. Capillary microscopy showed dilated capillaries in the toes of the operated side. It is possible that in this case the results may be attributed to reflex stimulation of the vasodilator fibers or to interruption of the vasoconstrictor fibers passing to the periphery in the peripheral nerve.

Mosser and Taylor,[34] as a result of their experiments, conclude that periarterial sympathectomy in dogs and cats has uniformly failed to produce hyperthermia. However, alcoholic injection of the sciatic nerve in sufficient strength to produce motor paralysis has resulted, in a constant hyperthermia.

The conclusions that one must draw from the foregoing discussion are that we have no proof that either the long vasomotor tracts or the long sensory tracts travel in the adventitia of the blood vessels. That there are vasomotor and possibly some sensory changes following the operation, there can be little doubt. We are not, however, justified in attributing these reactions to any specific attack made on the sympathetic fibers coursing in the sheaths of blood vessels. This position can be supported by experimental work and by the appearance of similar reactions to operative procedures which in no way approximate a thorough neurectomy of perivascular fibers. Furthermore, one must be critical in interpreting results. In some cases of trophic ulcers of both extremities, sympathectomy on one limb has been followed by beneficial results to both limbs. Similar results have occurred in Raynaud's disease when operation on one limb has been followed by bilateral improvement [35] It may be ventured in the light of our present knowledge that many of the clinical phenomena may be attributed to the enforced rest in bed, while other results may follow the beneficial effects of the reactive hyperemia of inflammation produced by local trauma and subsequent wound healing. Relief or diminution of pain may in some instances be due to interference with the conductivity of sensory nerves. Again, this temporary diminution of pain may lead to increased physiologic activity of voluntary muscles which is accompanied by active hyperemia. Psychic effects must be taken into account in a final analysis, and some benefit may be derived from the voluntary activity induced by the patient's desire to show improvement.

In spite of the fact that there are few diseases wherein pure or relatively pure vasomotor disturbances can be demonstrated, there is a real service to be rendered by the neurologist and surgeon in establishing a successful plan of attack on these vasomotor dysfunctions.

The clinical results of the present operation have been far from satisfactory. We may explain many failures as due to the lack of knowledge of the exact pathogenesis of many conditions for which the operation has been performed. In some instances the pathologic condition present has been such that it would seem impossible to produce marked physiologic reaction by any operation. In such vascular diseases as thrombo-angiitis obliterans, the essential pathologic condition consists of well marked organic changes, with organization of the thrombus occluding the vessel lumen. Likewise, it is not reasonable to expect any change in such organic diseases as primary or secondary arteriosclerosis. While these two conditions represent the extreme degree of organic disease of blood vessels, they serve as examples of the extreme demands made on this operation. In such conditions as causalgia, in which the pathogenesis is still in doubt and the condition seems to run a self limited course, it does not seem wise to attack the blood vessels. Lewis and Gatewood [36] have shown excellent results in these cases by injecting the peripheral nerve with 60 per cent alcohol. Recently, Taylor and Rice [37] have advocated the injection of the sciatic nerve with alcohol as a substitute for periarterial sympathectomy of the femoral or popliteal vessels.

In reviewing the literature, one is constantly reminded that the enthusiasm of the authors for the operation is not borne out by a critical analysis of their case reports. Too often the authors wax eloquent over the early improvement shown and trail off with an apologetic addendum that the apparent cure was only transient [38] This is particularly apparent in the reports of chronic ulcers, which show remarkable improvement during the hyperemic phase, but tend to recur with the subsidence of this reaction.[39]

Brandenburg [40] collected statistics from eight German surgeons reporting 103 cases. He states that although the majority of patients are benefited for a while, permanent good results are rare.

Hohlbaum [41] reports failure of the operation in cases of vasomotor disturbances due to nerve injury.

Leriche [42] himself states that in causalgia and trophic ulcers the results are not always complete; in senile gangrene poor, and in ascending neuritis and erythromelalgia a failure.

Winslow [43] reports three cases of thrombo-angiitis and one case of Raynaud's disease in which failure followed operation. I have performed the operation twenty-two times in twenty patients: In ten cases of thrombo-angiitis obliterans, one case bilateral; in seven cases of arteriosclerotic gangrene, one case bilateral; and one case each of Raynaud's disease, diabetic gangrene and chronic ulcer of the leg. Temporary improvement was noted in a considerable number, but relapse occurred in all except three, which showed but slight improvement. In a previous article [44] I have reported the use of sympathectomy with concomitant main vein ligation.

The recent visit of Royle and Hunter to this country stimulated renewed interest in surgery of the sympathetic nervous system, and several surgeons have followed their technic for ramisectomy and ganglionectomy with the idea of attacking the vasomotor fibers before their distribution in the peripheral vessels. Adson and Brown [45] have suggested that relief of vasomotor disturbances may be brought about by permanently depressing or destroying the overactive vasoconstrictor influences of the acral arterioles. This result, they believe, can be brought about in the lower extremity by lumbar sympathectomy This newer attack seems to have a more logical foundation than perivascular sympathectomy However, the gravity of the operative procedure itself, as described by Royle [46] and modified by Adson,[47] will be an enormous obstacle to its general adoption as surgical therapy

Periarterial sympathectomy has always been spoken of as a comparatively simple procedure, but there have appeared innumerable references to mishaps occurring during or following its performance Such accidents as wound infection,[48] perforation of the artery,[49] secondary hemorrhages,[50] false aneurysm,[51] thrombosis of the artery [52] and gangrene of the extremity [53] have been rather frequent

Even though we are compelled to admit that perivascular sympathectomy has not fulfilled the promises that seemed so alluring when it was first suggested, nevertheless, it has served a useful purpose in stimulating wide interest in the sympathetic nervous system and awakening the surgical profession to the possibilities in neurovascular surgery.

CONCLUSIONS

1. I am not prepared to accept either the theory or the practice of the present operation.

2 My exerience as well as the reports from other workers would seem to suggest that the operation should be discarded

3. A more careful study should be made of the sympathetic nervous system

4 An intensive study of the pathogenesis of various vascular disturbances should be made before operative procedures are resorted to.

5 The operation of periarterial sympathectomy carries with it some technical difficulties and is accompanied by not a few serious mishaps.

6. The substitution of ramisectomy and ganglionectomy for the present operation will greatly increase the operative risk.

7. The present operation has had a stimulating influence in broadening the general knowledge in this field of neurologic surgery, and has served to weld a closer bond between the neurologist and the surgeon.

this substance is present in the blood; also possibly the contraction by which they respond to the natural stretching force of the blood pressure.

Of these several factors, we are especially concerned with the continuous vasoconstrictor impulse which is the variable by whose modified activity it was hoped the caliber of peripheral vessels could be influenced, the point of attack having been principally directed to the interruption of the efferent fibers, thereby removing the control of the vasoconstrictor center over the peripheral vessels. The futility of securing interruption of any considerable number of fibers by removal of a segment of vessel sheath has been shown by Milko,[22] Schilf[23] and others, who secured no change in the blood flow in the extremity of a dog when the sheath of the femoral artery was stimulated. Wiedhopf[24] likewise found no plethysmographic changes in the foot of a dog following periarterial sympathectomy. Melzner[25] removed the perivascular sheath of the renal artery of a dog and found no histologic differences between the kidney that had been operated on and the kidney that had not. Bowing[26] showed that vasomotor reflexes are maintained after sympathectomy but are abolished when the peripheral nerves are cut.

With the accumulation of evidence that the effects of this operation are not due to interruption of the efferent tracts, it is suggested by Bruning[27] that they are due to interruption of afferent tracts which are likewise supposed to travel in the periarterial sheaths of peripheral blood vessels. Andre Thomas,[28] as early as 1917, suggested that deep sensations were transmitted in the nerves traveling in the vessel sheath. This explanation seemed plausible and helped to explain the disappearance of pain which has been noted frequently in patients who have been operated on. The experimental work of Friedrich[29] seemed to support this view, but the researches of Dennig,[30] who duplicated the work of Friedrich under better controlled conditions, demonstrates that no long vasodilator fibers nor long sensory paths travel in the adventitia of peripheral vessels. Wiedhopf's[31] researches seem to support the work of Dennig.

Another explanation has been offered for the hyperemia that follows operations on an extremity. It is fairly well known that stimulation of a sensory or mixed nerve produces a very decided vasomotor change in an extremity. In 1866, Loven[32] showed that stimulation of the great auricular nerve of a rabbit produces vasodilatation in the rabbit's ear. He also showed that stimulation of the anterior crural nerve of a dog produces local dilatation of blood vessels of the extremity, with vasoconstriction elsewhere and an increase in general blood pressure. These experiments speak for active vasodilator nerves which receive their impulses as a reflex through the dorsal root sensory fibers, or it is possible that they may be antidromal in type, corresponding in many ways to the "axon reflex" described by Langley.

Lawen[33] stretched the sciatic and saphenous nerves in an elderly patient as a remedy for arteriosclerosis and hypothermia of the foot. He produced a hyperthermia with some motor paralysis. Capillary microscopy showed dilated capillaries in the toes of the operated side. It is possible that in this case the results may be attributed to reflex stimulation of the vasodilator fibers or to interruption of the vasoconstrictor fibers passing to the periphery in the peripheral nerve.

Mosser and Taylor,[34] as a result of their experiments, conclude that periarterial sympathectomy in dogs and cats has uniformly failed to produce hyperthermia. However, alcoholic injection of the sciatic nerve in sufficient strength to produce motor paralysis has resulted, in a constant hyperthermia.

The conclusions that one must draw from the foregoing discussion are that we have no proof that either the long vasomotor tracts or the long sensory tracts travel in the adventitia of the blood vessels. That there are vasomotor and possibly some sensory changes following the operation, there can be little doubt. We are not, however, justified in attributing these reactions to any specific attack made on the sympathetic fibers coursing in the sheaths of blood vessels. This position can be supported by experimental work and by the appearance of similar reactions to operative procedures which in no way approximate a thorough neurectomy of perivascular fibers. Furthermore, one must be critical in interpreting results. In some cases of trophic ulcers of both extremities, sympathectomy on one limb has been followed by beneficial results to both limbs. Similar results have occurred in Raynaud's disease when operation on one limb has been followed by bilateral improvement.[35] It may be ventured in the light of our present knowledge that many of the clinical phenomena may be attributed to the enforced rest in bed, while other results may follow the beneficial effects of the reactive hyperemia of inflammation produced by local trauma and subsequent wound healing. Relief or diminution of pain may in some instances be due to interference with the conductivity of sensory nerves. Again, this temporary diminution of pain may lead to increased physiologic activity of voluntary muscles which is accompanied by active hyperemia. Psychic effects must be taken into account in a final analysis, and some benefit may be derived from the voluntary activity induced by the patient's desire to show improvement.

In spite of the fact that there are few diseases wherein pure or relatively pure vasomotor disturbances can be demonstrated, there is a real service to be rendered by the neurologist and surgeon in establishing a successful plan of attack on these vasomotor dysfunctions.

The clinical results of the present operation have been far from satisfactory. We may explain many failures as due to the lack of knowledge of the exact pathogenesis of many conditions for which the operation has been performed. In some instances the pathologic condition present has been such that it would seem impossible to produce marked physiologic reaction by any operation. In such vascular diseases as thrombo-angiitis obliterans, the essential pathologic condition consists of well marked organic changes, with organization of the thrombus occluding the vessel lumen. Likewise, it is not reasonable to expect any change in such organic diseases as primary or secondary arteriosclerosis. While these two conditions represent the extreme degree of organic disease of blood vessels, they serve as examples of the extreme demands made on this operation. In such conditions as causalgia, in which the pathogenesis is still in doubt and the condition seems to run a self limited course, it does not seem wise to attack the blood vessels. Lewis and Gatewood [36] have shown excellent results in these cases by injecting the peripheral nerve with 60 per cent alcohol. Recently, Taylor and Rice [37] have advocated the injection of the sciatic nerve with alcohol as a substitute for periarterial sympathectomy of the femoral or popliteal vessels.

In reviewing the literature, one is constantly reminded that the enthusiasm of the authors for the operation is not borne out by a critical analysis of their case reports. Too often the authors wax eloquent over the early improvement shown and trail off with an apologetic addendum that the apparent cure was only transient.[38] This is particularly apparent in the reports of chronic ulcers, which show remarkable improvement during the hyperemic phase, but tend to recur with the subsidence of this reaction.[39]

Brandenburg [40] collected statistics from eight German surgeons reporting 103 cases. He states that although the majority of patients are benefited for a while, permanent good results are rare.

Hohlbaum [41] reports failure of the operation in cases of vasomotor disturbances due to nerve injury.

Leriche [42] himself states that in causalgia and trophic ulcers the results are not always complete; in senile gangrene poor, and in ascending neuritis and erythromelalgia a failure.

Winslow [43] reports three cases of thrombo-angiitis and one case of Raynaud's disease in which failure followed operation. I have performed the operation twenty-two times in twenty patients: In ten cases of thrombo-angiitis obliterans, one case bilateral; in seven cases of arteriosclerotic gangrene, one case bilateral; and one case each of Raynaud's disease, diabetic gangrene and chronic ulcer of the leg. Temporary improvement was noted in a considerable number, but relapse occurred in all except three, which showed but slight improvement. In a previous article [44] I have reported the use of sympathectomy with concomitant main vein ligation.

The recent visit of Royle and Hunter to this country stimulated renewed interest in surgery of the sympathetic nervous system, and several surgeons have followed their technic for ramisectomy and ganglionectomy with the idea of attacking the vasomotor fibers before their distribution in the peripheral vessels. Adson and Brown [45] have suggested that relief of vasomotor disturbances may be brought about by permanently depressing or destroying the overactive vasoconstrictor influences of the acral arterioles. This result, they believe, can be brought about in the lower extremity by lumbar sympathectomy This newer attack seems to have a more logical foundation than perivascular sympathectomy However, the gravity of the operative procedure itself, as described by Royle [46] and modified by Adson,[47] will be an enormous obstacle to its general adoption as surgical therapy

Periarterial sympathectomy has always been spoken of as a comparatively simple procedure, but there have appeared innumerable references to mishaps occurring during or following its performance Such accidents as wound infection [48] perforation of the artery,[49] secondary hemorrhages,[50] false aneurysm,[51] thrombosis of the artery [52] and gangrene of the extremity [53] have been rather frequent

Even though we are compelled to admit that perivascular sympathectomy has not fulfilled the promises that seemed so alluring when it was first suggested, nevertheless it has served a useful purpose in stimulating wide interest in the sympathetic nervous system and awakening the surgical profession to the possibilities in neurovascular surgery.

CONCLUSIONS

1. I am not prepared to accept either the theory or the practice of the present operation.

2 My experience as well as the reports from other workers would seem to suggest that the operation should be discarded

3 A more careful study should be made of the sympathetic nervous system

4 An intensive study of the pathogenesis of various vascular disturbances should be made before operative procedures are resorted to

5 The operation of periarterial sympathectomy carries with it some technical difficulties and is accompanied by not a few serious mishaps.

6. The substitution of ramisectomy and ganglionectomy for the present operation will greatly increase the operative risk

7. The present operation has had a stimulating influence in broadening the general knowledge in this field of neurologic surgery, and has served to weld a closer bond between the neurologist and the surgeon.

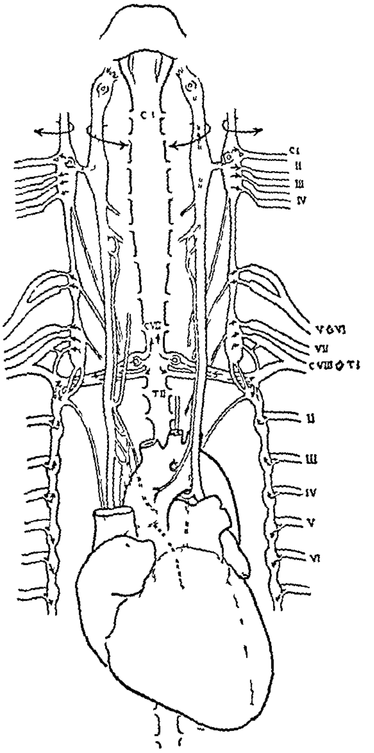
SYMPATHECTOMY IN ANGINA PECTORIS *

ELLIOTT C. CUTLER, M.D.
AND
JACOB FINE, M.D.
CLEVELAND

The pathologic process that gives rise to the clinical picture angina pectoris is of unknown etiology. Therefore, medical men have attempted symptomatic relief chiefly by rest and nitroglycerin, or by antispecific treatment when the disease has had a syphilitic origin. As these methods have been unavailing in many cases, it was natural to expect an attempt at symptomatic relief by surgical means, i. e., by interrupting nervous pathways carrying the painful stimuli. The belated efforts of surgeons in this field, in contrast to the early interference in comparable diseases, as tic douloureux, are due to our incomplete knowledge of the sensory pathways involved in cardiovascular symptomatology.



Connections of the heart with the central nervous system. The paired vagi are shown next to the cord with the ganglionated sympathetic chains external to the vagi. The connections of the sympathetic ganglions with the spinal nerves are drawn in. The origin of the depressor nerve in the superior sympathetic ganglion and in the upper ganglion of the vagus are represented with these fibers drawn in with dashed lines in the vagi and sympathetic ganglions. These fibers then branch away with the superior laryngeal nerve and finally travel free in the neck to end in the suprasigmoid portion of the aorta. The fibers running from the three cervical sympathetic ganglions medially and downward represent structures commonly called the upper, middle and lower cardiac nerves. These nerves are joined by many vagal fibers and fibers from the stellate and sometimes second dorsal ganglions to form a great network both in front and behind the aorta and base of the heart, in which in turn are embedded many sympathetic ganglion cells. Except for the connection of the vagi with the central nervous system in the brain stem, the connections between the stellate ganglion and the spinal cord at the level of the first dorsal nerve represents the only proved connection between the heart and the central nervous system.

The surgical treatment of angina pectoris was first proposed by Francois Franck[1] in 1899, but it was not until 1916 that Jonnesco,[2] a Bucharest surgeon, actually operated on a patient with syphilitic aortitis and angina, with complete relief from pain. C. H. Mayo,[3] however, observed a case of relief from angina in a man on whom he did a bilateral extirpation of the superior cervical ganglion in 1914, but he did not report it until 1925.

The theoretical considerations underlying the surgical procedure are briefly as follows: In order to abolish the pain of angina, we must interrupt the nervous arc involved, either on the efferent or on the afferent side. It is common knowledge that the vagi and sympathetic nerves comprise the entire innervation of the thoracic viscera, as shown in the accompanying illustration. As the pain of angina arises in the thoracic viscera and is referred to the corresponding somatic segments of the skin, it is obvious that the stimuli giving rise to the substernal pain must pass through the afferent sympathetics passing to that portion of the spinal cord which supplies somatic sensation to the sternum, upper chest and the upper extremities. The anatomic and physiologic investigations of Gaskell,[4] Langley[5] and others have demonstrated that the entire visceral, afferent as well as efferent, sympathetic fibers supplying the heart, superior mediastinum and the rest of the body cephalad to these are all concentrated in a great terminal—the great thoracic (stellate) ganglion. Hence, bilateral extirpation of this structure would completely denervate the heart and aorta of their sympathetic supply. The entire cervical sympathetic system has been shown by Langley[6] and Ranson[7] to be purely efferent and can be made completely functionless by a similar procedure. There is no need to consider the parasympathetic innervation, i. e., vagus, in this connection. It could not be effective in causing pain referred to the chest, for the somatic afferent fibers of this system have no distribution in this region. Wenkebach and Eppinger,[8] nevertheless attacked the depressor nerve in the hope of relieving the pain of angina pectoris. This nerve, as a result of the work of Koster and Tschermak[9] and more recently of Einthoven, is known to be a purely sensory nerve innervating the aorta. That it can in any way be associated with the anginal syndrome seems questionable, however, since the response to its stimulation consists in a fall of the blood pressure and a slowing of the heart. We know clinically that as a rule the blood pressure rises during an anginal seizure, so that one should assume, if the depressor nerve bears any relation to the disease, that it fails to respond to an

overstretching of the aortic wall instead of responding excessively. Moreover, clinical pursuit of this procedure has not been very vigorous since it was proposed, because the nerve is difficult to find and when ablated is not productive of any significant improvement.[10]

On the other hand, the operation proposed by Jonnesco, which consists in removal of the stellate ganglions and all sympathetic ganglions cephalad to this, has in many cases given gratifying results. From what has already been said, however, his operation is unnecessarily extensive, since removal of anything in addition to the first thoracic ganglion is superfluous on theoretical grounds. But Coffey and Brown [11] discovered that removal of the superior cervical ganglion was often effective in removing the anginal pain. As this has been substantiated by the subsequent experience of others, it becomes necessary to explain such relief by supposing that this ganglion is involved in the nervous arc producing the anginal seizure and, since it contains only efferent neurons, that it is on the motor side of the cycle resulting in the production of the pain.

But no one has yet observed any noticeable physiologic effect on the heart or aorta as a result of stimulation or removal of this ganglion. The suggestion then presents itself that, since relief has in many cases been obtained by the most varied procedures, all of which have failed nearly as often as they have been successful, we are dealing with a symptom not directly referable to an organic lesion, and that, therefore, many cases of angina are neuroses which have been relieved by the suggestive power of surgery. However, few persons in contact with patients suffering from angina will be impressed by such a possibility; so that we are left with the unavoidable conclusion that there is something common to all the surgical procedures attempted that is responsible for the relief that unquestionably is being secured by surgical intervention in about 60 per cent of the cases. What that common factor is remains for the future to expose.

But, in spite of the gains being secured by surgery, there are certain objections offered to the procedure on the ground that we may be producing by nerve ablation irremediably disturbances of cardiac function or injury to the myocardium, etc.[12] These objections can be readily disposed of by the available experimental and clinical evidence that such surgical procedures in no way incapacitate the heart (clinical, Jonnesco [13] and others;[14] experimental, Cannon [15] and others [16]).

Before we can correctly evaluate the results of sympathectomy in angina pectoris, we must be sure that the cases in which operation has been done have been correctly diagnosed, and we must exclude extraneous but often necessarily concomitant factors that may have influenced the ultimate result. It is obvious from the literature that frequently cases are being chosen for operation concerning which the diagnosis of angina pectoris is at least doubtful, if not at times quite incorrect. In this connection we should bear in mind that angina pectoris clinically, if not pathologically, is a definite disease with its own characteristic group of symptoms that can be differentiated from other types of cardiac and chest pain. This frequently requires considerable experience and prolonged and mature study and deliberation. One of the most frequent syndromes with which it is confused is coronary thrombosis. Obviously, operation in such cases will only tend to discourage surgeons from a procedure that may in time come to have a very definite position in cardiac surgery. It must be borne in mind that angina pectoris is a disease that is not in any way necessarily associated with demonstrable cardiac dysfunction. It may sometimes prove necessary to give relief to a patient with angina who has at the same time some degree of cardiac embarrassment, but in the present experimental stage of the procedure it is hardly correct to allow such cases to enter into a consideration of the advisability of the procedure, since the dangerous condition of the heart itself and the extra load of surgical trauma are bound to warp the results and becloud the issue, which is: Can surgical intervention remove the symptom of pain without at the same time predisposing the circulation to any consequent disability? At the present time a sufficient number of cases have been reported in the literature to enable us, with the help of our own clinical experience on the subject, to draw a few conclusions as to the value of the operation. After we have deleted from the reported cases those which we believe have been advisedly selected for operation, there remain about eighty cases (up to six months ago) of true angina pectoris in which operation was done by six different procedures.[17] Certainly many more cases have been done (eighty-three by Leriche alone [18]), and many more are being done. From our own experience as well as from a careful survey of the literature it becomes increasingly evident that much indiscriminate surgery is being and will be done in this field unless the indications for surgery are duly considered and pointed out. It appears to us from a survey of the results achieved to the present that the most successful operation will probably prove to be the partial Jonnesco procedure; i. e., ablation of the stellage ganglion by the technic either of Jonnesco or of A. K. Henry.[19] There is no doubt that brilliant results will continue to be secured by the less formidable operation of superior cervical sympathectomy, but on theoretical and clinical grounds the more reliable one in the long run will prove to be the former.

Our own experience, though limited, may serve to illustrate certain points in the matter under discussion. It includes purposefully what may seem to be a variety of clinical conditions in that one of the patients is a youth of 19, suffering from marked aortic insufficiency of rheumatic origin. In our understanding of the disease angina pectoris, we are inclined to accept the view of Allbutt, and it seemed that cases of this type might be of the greatest assistance in appreciating the etiologic condition. This patient therefore, was submitted to operation with the hope that more light would be thrown on the focus of the disease in angina pectoris. In such a case, serious disease of the coronary arteries and myocardium seemed ruled out. And we knew that there was definite disease of the cusps of the aortic valve.

The following case reports include only the positive findings and serve merely to outline their course. All of these patients are controlled cases in the sense that they have had frequent, careful follow-up examinations, including vital capacity determinations, roentgen-ray studies and functional tests. They serve the purpose here merely of a skeleton on which one can hang the necessary facts for such an abbreviated discussion of this topic.

REPORT OF CASES

Case 1.—A man, aged 59, married, a printer, an inveterate pipe smoker, for ten months suffered substernal distress on effort. For four months he had an agonizing, gripping, viselike pain, increasing in severity and coming on with slight exertion and spreading to the neck and left arm, never to the right, relieved by nitroglycerin. There was no dyspnea, edema or other symptoms. For one month he had been confined to the house.

He was relatively normal for his age. His heart was of normal size: rhythm was regular, and there were no murmurs. The blood pressure was: systolic, 132; diastolic, 90. Electrocardiographic, roentgen-ray, blood and urinary studies were normal. There was no evidence of syphilis.

June 21, 1923, resection of the left superior cervical sympathetic ganglion was done. After three and one-half months he returned to work as a printer, walking more than a mile to his office. He continued to suffer from mild substernal distress, coming on with exertion. It was immediately relieved by nitroglycerin, which he took almost daily. There was no return of severe attacks. Symptomatically he was greatly relieved, and was very grateful. He died suddenly, Jan. 26, 1926, after an attack of severe pain lasting six hours. He was not personally observed, but death was apparently due to coronary thrombosis.

Case 2.—A youth, aged 19, single, had had rheumatic fever at 7 years of age, during which period he was confined to bed for several months. A year following this, the tonsils and adenoids were removed. There were repeated attacks of rheumatic fever up to the age of 16, at which time he was admitted to a hospital, complaining of heart trouble. Examination at that time showed marked enlargement of the heart, with a rough, blowing systolic murmur and a loud blowing diastolic murmur; the pulse was of the Corrigan type. The blood pressure was: systolic, 165; diastolic, 0. A diagnosis of aortic insufficiency and mitral insufficiency was made. Shortly before admission, the patient had begun to be troubled with attacks of substernal pain. This pain was consistently relieved by nitroglycerin. During the next three years there were frequent readmissions to the hospital, the complaint varying between weakness, loss of weight, shortness of breath and substernal pain. The patient was always improved symptomatically by rest in bed, but finally returned to the hospital complaining that the pain was becoming intolerable. It seemed to commence in the region underlying the midsternum. It progressed through to the back, sometimes to the right axilla, never down the left arm, and it was always relieved by nitroglycerin. At the time of last admission there were many attacks daily, and these were of great severity. The pain usually had its onset in some form of physical exercise. It was not relieved by digitalis therapy.

The youth appeared healthy, and the diagnosis of aortic insufficiency was apparent on the most superficial examination. There was a very wide area of cardiac impulse, and the pulsation in the neck was forceful and visible at a great distance. The heart was enormously enlarged, the major enlargement being in the region of the left ventricle. This was all confirmed by roentgen-ray and electrocardiographic studies. A vital capacity estimation showed a 25 per cent reduction from the expected normal.

In view of the central location of the pain, it was decided to perform sympathectomy on both sides. The operations were done at two sittings two weeks apart (Oct. 3 and Oct. 18, 1923). On the left side the superior cervical ganglion, after division of the ramus communicans inferiorly of its many lateral branches, was divulsed and removed. On the right side a portion of the communicating bundle between the upper and middle ganglions and of the superior candiac nerves was resected. The wounds healed without complication. There was the usual enophthalmos and myosis of the pupils.

Recent reports from the patient state that he is working, and that for at least six months he has taken no nitroglycerin. There are minor attacks of precordial pain, but none of great severity. The patient is up and around and at work daily, walking considerable distances. What pain he has is associated with some palpitation and dyspnea, but he states that it is a different kind of pain from what he suffered previously. He still complains of some distress in the left side of his face with chewing. It would appear as if the continued improvement over an interval of two and one-half years bore some relation to the operative procedure.

Case 3.—A man, aged 72, married, had for three or four years suffered with substernal oppression on exertion, increasing in severity, and lately accompanied with a dull, crushing pain in the left shoulder and arm. In recent attacks he felt that he was dying.

There was slight cyanosis. The heart was of normal size; there was a faint systolic murmur, and an accentuated aortic second sound. The blood pressure was: systolic, 170; diastolic, 70. Vital capacity was decreased. Blood, urine and electrocardiographic studies were normal.

Jan. 7, 1924, the upper, middle and lower left cervical sympathetic ganglions were removed. He is now active and states that he is much improved. The blood pressure is: systolic, 160; diastolic, 80. The heart sounds are unchanged. On rare occasions with exertion, as when working in the garden, there is a vague sense of constriction in the chest. He is satisfied. He rarely takes nitroglycerin for the pain. Though never a very severe case, it seems as if his condition has been improved since the operation two years ago.

Case 4.—A man, aged 60, married, a merchant, twenty months previously, without similar attacks, after an unusually long walk in deep snow had a very severe and alarming pain, substernal, vicelike, into the root of the neck and down the left arm. Subsequent attacks became increasingly frequent and on slight exertion. There was no dyspnea.

The patient appeared vigorous. The blood pressure was: systolic, 125; diastolic, 80. The heart was of normal size, rate and action. Roentgen-ray, exercise, electrocardiographic, blood and urine studies were normal.

Nov. 22, 1924, division of the left superior cardiac nerves and of the trunk between the upper and middle ganglion was done. After six months the patient was readmitted to the hospital, since we became convinced that the return of distress was equal to the previous complaints. June 6, 1925, resection of the left middle, inferior and stellate ganglions was done. When seen in consultation with his family physician, October 26, his general condition was excellent. He was cheerful, had suffered from no severe attacks, and was not taking nitroglycerin, but objected because he could not walk as far as he used to. Without any warning, but preceded by mental worry, he was suddenly seized at 2:30 a. m., Jan. 7, 1926, with severe, agonizing, substernal pain, which radiated into his arms (unfortunately no close observation was made as to whether the pain was greater in the right or left side). He died within a few hours, and his physician described the pain and attack as "truly anginal." Although there were no records of the behavior of his pulse and pressures, it seems reasonable to conclude that death was due to coronary thrombosis.

Case 5.—A man, aged 65, married, a merchant, for one year had a crushing, viselike pain beneath the sternum and to the left part of the chest, left shoulder and the root of the neck. There was an aura of great distress and threatened disaster. He had lost 40 pounds (18 Kg.). Nitrites gave relief temporarily.

The patient was emaciated, desiccated, and extremely apprehensive. The left ventricle was enlarged; there was no evidence of widening of the aortic arch. There were no cardiac murmurs. The pulse was regular. The blood pressure was: systolic, 140, diastolic, 80, rising to 180 with attacks. Electrocardiographic studies were normal. A functional test showed good response to effort.

May 23, 1925, a left cervicothoracic sympathectomy[20] was done. The patient died, May 31, eight days later. Immediately after operation there occurred curious and inexplicable periods of apnea, with rapid pulse and normal pressures. Gradually the patient became totally disorientated and mentally exhausted, the pulse gradually deteriorated, and death supervened with respiratory failure. No necropsy was permitted. Explanation periods of apnea were wanting. The marked mental symptoms seemed to indicate sclerosis of the cranial vessels, with softening of the brain.

CASE 6.—A man, aged 54, married, a steward, for one and one-half years had been incapacitated by attacks of substernal pain. It often extended into the root of the neck, the back and down the left arm. With the pain was a sense of impending disaster. He was unable to work, since effort brought on pain. Relief was obtained from nitroglycerin.

He was a rugged, vigorous man. The heart was normal in size and action. The blood pressure was: systolic, 128; diastolic, 75. There were no murmurs. The Wassermann reaction was negative. Blood, urine and electrocardiographic studies were normal.

April 27, 1925, a left cervicothoracic sympathectomy was done. After two weeks of freedom and with the recommencement of exercise, pain began to return, but this time it was situated just to the right of the sternum in the second and third interspaces, with radiation into the root of the neck. The pain was very severe and alarming, and was accompanied by peculiar attacks of apnea. May 29, a partial right cervicothoracic sympathectomy was done, with removal of the middle and inferior cervical ganglions and stellate ganglion.[21] Following the last operation, the patient at first was much more comfortable. He suffered from vague burnings around the left ear and right shoulder. Breathing was unaffected by pain as formerly. It was unnecessary to take nitroglycerin. He took up smoking again. With increasing effort as he began to walk about and eat more, he had a return of distress beneath the right border of the sternum, but never so severe as previously. Nitroglycerin was given, with relief. Jan. 8, 1926, he walked to the office to discuss his case, had regained 30 pounds (13.6 Kg.), was cheerful, and was greatly relieved. January 24, he was seized with severe agonizing pain just to the right of the sternum. Nitroglycerin alone gave relief. He has lost appetite and does not sleep well. The pulse remains regular. He is considerably depressed. The continuance of rightsided pain may be evidence that the stellate ganglion on this side was not completely extirpated. The downward tendency in the last two months offers a bad prognosis and may bespeak advanced coronary sclerosis.

CASE 7.—A man, aged 64, married, a clerk, up to eight months ago had been unusually active. The original symptoms were indigestion and substernal distress; later, difficulty in getting the breath, and a sense of constriction of the chest. Still later, there were attacks of pain originating beneath the sternum and radiating to the root of the neck and down both arms. The pain was always greater on the right side. The patient reacted to the pain by getting up and moving the arms about. Recently the pain had been crushing, very severe, not relieved by morphine, and there was constant substernal distress.

The patient was spare but well developed. The heart was slightly enlarged, the aortic arch a little widened. The pulse ranged from 80 to 90. The blood pressure was: systolic, 154; diastolic, 78. No cardiac murmurs were heard. Vital capacity and electrocardiographic, blood and urine studies were normal. Response to the exercise test was good.

Nov. 18, 1925, right cervicothoracic sympathectomy was done (the right side was operated on first, since the history of painful attacks emphasized the greater intensity of the pain on this side). The immediate postoperative course was satisfactory. The patient was sent home for Thanksgiving. December 4, left cervicothoracic sympathectomy was done. Except for slight twinges of pain in the jaws, shoulders, etc., as by-effects of the operation, the condition has been satisfactory. There has been no substernal pain. The patient is beginning to walk about, satisfied, and apparently considerably improved. He was last seen, March 18, 1926. After a mile walk and climbing up a long and very steep flight of stairs, the pulse was 88; systolic blood pressure, 165; diastolic, 90; vital capacity, 25 per cent decrease; no dyspnea, and no other symptomatic complaint.

COMMENT

From a consideration of these cases it becomes evident that a single or bilateral extirpation of the superior cervical ganglion or of the entire cervical chain and first dorsal ganglion will frequently give temporary complete or partial relief and often will fail. The complete operation is less likely to fail entirely, however, than simple superior ganglionectomy. (Case 4 showed return of pain after the simple operation, but was apparently improved following the secondary removal of the stellate ganglion on the same side.) In certain cases it appears that what was considered a leftsided angina before operation has been converted into a rightsided angina by a left Jonnesco procedure (case 6). This, however, means that the leftsided angina was relieved and the residual rightsided angina, not noticed by the patient preoperatively because of its comparative insignificance, now remains. Contrary to our conception of the anatomic factors involved, from which it would seem that proper sensory nerve ablations ought to stop the pain immediately afterward, certain patients eventually totally relieved, even after complete bilateral Jonnesco procedure, will still have pain, as a rule reduced in severity, postoperatively for a few weeks or months. This is ample evidence to indicate the insufficiency of our knowledge concerning the sensory innervation of the heart.

We have in no case observed any deleterious effects on the cardiac capactiy of the patient as a result of operation. A few have expressed the opinion that cases of syphilitic angina are particularly dangerous cases for operation.[22] It is difficult to understand why sympathectomy should be dangerous in these cases. A general anesthetic and prolonged surgical trauma may well be deleterious, but these are matters that enter into consideration as a routine in any case of syphilitic cardiac disease in which an operation is contemplated. When these dangers are duly cared for, a case of syphilitic angina should benefit from the operation as certainly as any other type of case.

The cases that are particularly dangerous in our experience are those which present advanced cerebral arteriosclerosis combined with severe coronary disease. They will not tolerate any surgical procedure well, and it seems as if sympathectomy makes them definitely worse, although it may relieve the pain (case 5).

Among the most distressing postoperative complications of the procedure are the by-effects of sympathectomy, which seem to be directly proportional to the degree of nerve resection. The Horner syndrome is a minor defect that compensates itself in time. But particularly annoying are the pains that are felt in the shoulder, neck, face, jaw and arm on the side on which operation is performed. In the jaw, especially along the ramus, and in the temporomandibular joint, the patient experiences a severe pain especially at the onset of a meal, and it may persist throughout the period of food ingestion in severe cases. There is a constant ache in the shoulder or scapula and down the arm, particularly at night, which is difficult to relieve except by narcotics or local counterirritants. Areas of hyperesthesia on the face, ear or neck will vary, as do those of anesthesia, with the amount of injury done to the cervical plexus during the operation. These symptoms vary in severity and extent of distribution in different cases, and may be so distressing as to make the cure seem worse than the disease. One patient of ours compared the terrible feeling in his entire left arm to a sensation of an infinite number of "slivers" sticking into it. Because of the transitory nature of these symptoms, it seems that they may be due to one of several possibilities—the altered vasomotor control of the organs and tissues deprived of their involuntary nerve supply, or irritation of the somatic sensory neurons of the spinal and cerebral ganglions as a result of neuronic degeneration of the severed sympathetic nerves.

---

[20] The term cervicothoracic sympathectomy we use to describe the complete Jonnesco operation, with removal of all the cervical and the first thoracic or stellate ganglions.

[21] There was some doubt at the operation in this case whether all of the stellate ganglion was removed. Subsequent developments add evidence to make us feel that not all the afferent fibers were interrupted.

[22] Levine and Newton (footnote 14).

That surgery will come to have a definite place in angina pectoris seems promising, but it is impossible as yet to say definitely which is the most desirable procedure of those proposed. We lean in favor of the partial Jonnesco procedure, unilateral or bilateral, depending on the individual case.

Unfortunately, this is not a subject susceptible of laboratory investigation beyond the point of establishing the possible location of the extrinsic nervous connections of the heart. It should be remembered by all who would shoulder the responsibility of operating on such patients that this study is still in its experimental stage and that only those who are carefully studied and carefully selected before operation and are followed until the end result is known can be justifiably submitted to operation.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. FORBES AND COBB; RANSON; DAVIS AND KANAVEL; MC NEALY, AND CUTLER AND FINE

Dr. Herbert E. Coe, Seattle: Royle and Hunter opened up a new phase in the surgical treatment of the spastic paralyses, and this was followed by the usual wave of hyperenthusiasm. Dr. Davis has sent the pendulum to the other extreme of its swing when he says that they have failed completely to confirm the work of Royle and Hunter. This should put an effective check on ill advised surgery. Does not the paper as a whole, however, leave too pessimistic an impression? The ability of Hunter and Royle is widely recognized throughout the scientific world. It does not seem reasonable that whatever improvement they have reported in these spastic cases has been due solely to enthusiasm, suggestion or autosuggestion. The comment of the authors as to the possible causes of this improvement deserves careful study. Whatever the cause of the improvement, whether it is temporary or permanent, psychologic or physiologic, it may be stated definitely that some degree of improvement has occurred in some cases in which surgery has been done on the sympathetic nervous system. Why do we hear such conflicting reports? Dr. Davis has placed his finger squarely on the essential point when he reminds us that we do not know the nature of muscle tone and that we have no method of measuring it. This refers the question directly back to the physiologist, where it must remain until muscle tone is better understood and a method of measurement is devised which eliminates as completely as possible the personal equation. Those of us who have the opportunity of studying these cases must bear constantly in mind the four cardinal indications, all of which must be present before surgery of the sympathetic system may be even considered—adequate mentality, a clear nerve pathway from cortex to end-organ, no physical obstruction to motion, and the inability to relax quickly. When these four indications are present, and when the case admits of reasonable control and accurate record, it would seem advisable to continue the observation of surgical results. Finally, from the point of view of the spastic patient in general, the most valuable result of this work is not the variable amount of improvement in the 5 or 10 per cent that may come to operation, but rather what we may term a by-product. It is heartless to drive these patients into the hands of charlatans with the curt prognosis "hopeless," for we have had recalled to us, and emphasized, the distinct improvement that may be obtained in the large proportion of cases by tried and proved orthopedic measures and by muscle training and reeducation.

Dr. Charles S. Venable, San Antonio, Texas: Most certainly all of the weight of evidence from the anatomic, physiologic and histologic standpoint is against sympathectomies. On the other hand, there must have been some clinical improvements or possibly some cures to have incited so much interest and so much research. I have lost some of my enthusiasm and possibly a little of my optimism in the ultimate curative end-results to be obtained by what one may speak of as broadcasting sympathectomies. But, on the other hand, when one has seen the entire relief from the severe pain in the painful stump which had previously been subjected to alcoholic injections or further resection, or when one has seen an atrophic ulcer which had been treated over a great number of years and in a great many ways heal and remain healed, one is encouraged, for lack of possibly something else to do, to repeat this procedure because nothing else is offered. In cases of Raynaud's disease, of which I have had five, the primary result is the prompt relief from pain and apparently a very prompt tendency, due to vasodilatation, of the ulcer to heal. In two of these cases the ulcers have healed and remained healed for varying lengths of time. One great advantage seems to be the possibility of amputation at a site of election rather than the necessarily high amputation we have had to practice heretofore. In cases of diabetic gangrene I have been able to do amputations below the knee with prompt stump healing, which I have done at a period of election, from ten to fifteen days after the sympathectomy. In one instance it was four days after the sympathectomy. I think that we should at least feel sufficient encouragement to go on with the investigation, and clinically I am afraid that I am going to be the culprit until our friends investigate us and either prove us so entirely wrong that all clinical evidence seems to go the other way, or agree and come along with us.

Dr. Samuel Clark Harvey, New Haven, Conn.: It is very apparent that there is no definite correlation between the anatomic and the physiologic findings that Dr. Ranson has presented, and the clinical results that have been obtained by the operative procedures so far employed, and particularly the operative procedure of Coffey and Brown. I should like to know more about the position of the sensory fibers in the sympathetic tract. Dr. Ranson has spoken of the physiologic and clinical evidence, which seems not at all complete. The clinical evidence consists of a few isolated observations which have been thought of as analogous to the somatic sensory system. I do not know that necessarily the lack of pain and response to the ordinary forms of stimulation employed at operation in the sympathetic system rule out the afferent impulses. The histologic evidence should be given more definitely, and I should like Dr. Ranson to tell us the evidence that he has from the histologic standpoint as regards the sympathetic sensory tracts. It is very apparent that the procedure employed clinically, and undoubtedly with palliative success, is of considerable importance. As to the selection of cases, we should be conservative. I do not feel that those cases that are diagnosed as coronary thrombosis should be ruled out. There are instances in which the outcome is very problematic, and certainly these should not be subjected to a prolonged and severe operative procedure under general anesthesia. As to the choice of operation, the less severe procedure should be employed first. The operation of Coffey and Brown, avulsion of the superior sympathetic ganglion or the division of the superior cardiac nerve and of the sympathetic trunk, is a relatively easy procedure which can be carried out perfectly well under local anesthesia, and as a tentative attack should be employed in each instance. Dr. Cutler did not lay sufficiently great emphasis on the fact that certain embarrassing sequelae may occur in any type of sympathectomy, the most embarrassing being the curious form of paresthesia analogous to or resembling Sluder's neuralgia. This may be very bothersome. Without doubt this operation has produced some results, perhaps not curative but certainly palliative. It is a purely empiric procedure, for the moment, not based on sound anatomic or physiologic reasoning. It is an experimental procedure on man, and such procedures on man should be carried out by those who are so situated as to make them scientific experiments. I do not think that the procedure is yet so sufficiently standardized as to justify employing it as a common therapeutic procedure. Dr. Cutler's paper exemplifies the study and care in the follow-up of the cases that is necessary, and these should be employed by any one who carries out this operative technic.

Dr. Walter B. Coffey, San Francisco: Five years ago I severed the superior cardiac nerve and the main branch of the sympathetic in a patient suffering from frequent attacks of angina. Physiologists claimed that there were no fibers of sensation as high as the superior ganglion. The fact remains, however, that the eight or ten attacks a day in my case ceased. *This operation has accomplished all that* any of the numerous procedures more complicated and dangerous have done with equally less disturbance and less mortality, for attacks have recurred after unilateral and bilateral resection of the stellate ganglion. I have now operated in about thirty-five cases with encouraging results. Four times I had to resect on both sides. I cannot emphasize too strongly that surgeons should not attempt the procedure without the advice of good clinicians. No patient on whom I have operated has died of an attack of angina. The few deaths were from an underlying organic lesion. I have experimented on animals and done many dissections. My assistant at that time, Dr. John Humber, now assistant professor of anatomy at Tulane, has continued the dissections, using a technic, tried at operation by me, of inflating the ganglion. Such inflation spreads out through the various branches and fibers connected with the ganglion. The dissections show connections and collaterals not previously demonstrated. In some cases, we found the superior ganglion high up in the angle close to the jugular foramen, and in many instances I severed the upper pole of the ganglion. *This would leave the carotid and* jugular branches with its collaterals to the carotid plexus and tympanic plexus. It may be the explanation why we get pain in some of these cases due to impulses through collaterals. The tympanic plexus is the most important relay station in the sympathetic system. I am quite certain that where these two branches from the upper pole, that is, the internal carotid and jugular, were severed favorable results were obtained. In a severe case of angina, the upper sympathetic system was thoroughly inflated with triple distilled water. The angina attacks disappeared, but a remarkable incident occurred on the night of the operation. The patient developed Cheyne-Stokes respiration. I could account for this only through the spreading of the fluid through a branch (which I frequently find) from the superior ganglion to the phrenic to the vagus through the connecting branches.

Dr. Alexander Lambert, New York: Sympathectomy by several different operations has been successful for the relief of anginal pain, but the same surgical procedure in one man has not relieved the pain in another. The variation in man of the pathways of the sensory nerve fibers is as varied as are the opinions as to what is best to do. It is not known which are the usual sensory pathways in man. The opinions of Danielopolu and the French observers differ from those expressed by Dr. Ranson and Dr. Cutler. The operation of sympathectomy has a low death rate, but when the stellate ganglion is removed, there is a distinctly greater death rate from the immediate effects on the patient than in any of the other operations. If this stellate ganglion is removed, about one fifth of the patients die of acute edema of the lungs soon afterward. The success of the various operations may be due, not to cutting of the sensory fibers, but to breaking up of the reflex arc, and a prevention of excessive stimulation of the vasoconstrictor reflexes. All this doubt as to what may be the result of any given operation of sympathectomy emphasizes the wisdom of trying a procedure, previous to operation, which stops the pain where it expresses itself on the body. All sensory nerves coming from the viscera go through some spinal nerve to the spinal cord by way of the white rami; these white rami occur only from the first dorsal to the fourth lumbar; therefore, when pain comes from the heart, it goes into the spinal cord through one of these nerves. All sensory nerves go through the posterior root ganglion of these spinal nerves, and this posterior root ganglion can be reached and the sensation of pain can be blocked off in that root ganglion. This has been done in New York by Dr. George Swetlow with marked success. It is not a difficult operation, it does block off the pain where it shows itself in the body segment, and it is the relief of pain *that the patient seeks. It is asserted that the pain of angina* is a warning, and a protective sensation: It is well to remember that the pain is the other man's pain, not yours, and he should be the one to decide whether or not it should be removed, especially since Bayliss has shown that through the sensory nerves the vasoconstrictor reflexes cause the danger in the angina. If these vasomotor reflexes can be cut off with the cessation of pain, the advantage is vastly greater than the mere relief of the pain. Most patients in whom the pain has been relieved by sympathectomy have shown distinctly an increased ability for exertion without excessive cardiac disturbance, which they did not possess previous to operation. Thrombosis of the coronaries, or coronary disease, does produce pain, and not all anginal pain comes from the aorta alone. It is also a curious fact that 25 per cent of those suffering from coronary disease have their expression of it in the epigastrium in the nerves that come out from the second to the ninth dorsal vertebrae running into the plexuses on the esophagus, lungs and heart. One cannot by any sympathectomy stop this expression of pain. In the epigastric pain, therefore, one is reduced to the necessity of blocking it, if one desires to help it. In only 10 per cent of patients suffering from coronary disease does the pain go down the arm and sympathectomy have a chance to help.

Dr. Arthur Steindler, Iowa City: This symposium is a general attempt to break down some of the claims that have been made by Royle and Hunter, and if it is, a thorough job has been done. I have been very much impressed with what I have heard today, but when we heard Royle and Hunter, we were likewise deeply moved by the thoroughness and earnestness of their work. I feel that while this investigation into their work is going on, it is proper to investigate the investigation. From the physiologic point of view, the matter stands as it did some time ago, namely, that it is acknowledged that the sympathetic nervous system has a direct influence on the innervation of the peripheral or skeletal muscles; but the question of how this innervation is arranged is still unanswered. I regret that the experiments have not been extended to the fowl and to the seagull, in which spastic tone is especially noticeable and spastic tone is a definite function and not an obstacle, as it is in man. I believe it the strongest point in the physiologic investigations of Hunter that special sympathetic control was to be found in these birds that soar and that have to keep their wings in a special state of contracture for an unbelievably long time. When it comes to the clinical evidence, it seems to me that the cases in which we have succeeded must be explained first before we can dispose of sympathetic innervation as a physiologic factor. I am greatly impressed with what I have heard today, but it seems to me that there particularly annoying are the pains that are felt in the shoulder, neck, face, jaw and arm on the side on which operation is performed. In the jaw, especially along the ramus, and in the temporomandibular joint, the patient experiences a severe pain especially at the onset of a meal, and it may persist throughout the period of food ingestion in severe cases. There is a constant ache in the shoulder or scapula and down the arm, particularly at night, which is difficult to relieve except by narcotics or local counterirritants. Areas of hyperesthesia on the face, ear or neck will vary, as do those of anesthesia, with the amount of injury done to the cervical plexus during the operation. These symptoms vary in severity and extent of distribution in different cases, and may be so distressing as to make the cure seem worse than the disease. One patient of ours compared the terrible feeling in his entire left arm to a sensation of an infinite number of "slivers" sticking into it. Because of the transitory nature of these symptoms, it seems that they may be due to one of several possibilities—the altered vasomotor control of the organs and tissues deprived of their involuntary nerve supply, or irritation of the somatic sensory neurons of the spinal and cerebral ganglions as a result of neuronic degeneration of the severed sympathetic nerves.

That surgery will come to have a definite place in angina pectoris seems promising, but it is impossible as yet to say definitely which is the most desirable procedure of those proposed. We lean in favor of the partial Jonnesco procedure, unilateral or bilateral, depending on the individual case.

Unfortunately, this is not a subject susceptible of laboratory investigation beyond the point of establishing the possible location of the extrinsic nervous connections of the heart. It should be remembered by all who would shoulder the responsibility of operating on such patients that this study is still in its experimental stage and that only those who are carefully studied and carefully selected before operation and are followed until the end result is known can be justifiably submitted to operation.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. FORBES AND COBB; RANSON; DAVIS AND KANAVEL; MC NEALY, AND CUTLER AND FINE

Dr. Herbert E. Coe, Seattle: Royle and Hunter opened up a new phase in the surgical treatment of the spastic paralyses, and this was followed by the usual wave of hyperenthusiasm. Dr. Davis has sent the pendulum to the other extreme of its swing when he says that they have failed completely to confirm the work of Royle and Hunter. This should put an effective check on ill advised surgery. Does not the paper as a whole, however, leave too pessimistic an impression? The ability of Hunter and Royle is widely recognized throughout the scientific world. It does not seem reasonable that whatever improvement they have reported in these spastic cases has been due solely to enthusiasm, suggestion or autosuggestion. The comment of the authors as to the possible causes of this improvement deserves careful study. Whatever the cause of the improvement, whether it is temporary or permanent, psychologic or physiologic, it may be stated definitely that some degree of improvement has occurred in some cases in which surgery has been done on the sympathetic nervous system. Why do we hear such conflicting reports? Dr. Davis has placed his finger squarely on the essential point when he reminds us that we do not know the nature of muscle tone and that we have no method of measuring it. This refers the question directly back to the physiologist, where it must remain until muscle tone is better understood and a method of measurement is devised which eliminates as completely as possible the personal equation. Those of us who have the opportunity of studying these cases must bear constantly in mind the four cardinal indications, all of which must be present before surgery of the sympathetic system may be even considered—adequate mentality, a clear nerve pathway from cortex to end-organ, no physical obstruction to motion, and the inability to relax quickly. When these four indications are present, and when the case admits of reasonable control and accurate record, it would seem advisable to continue the observation of surgical results. Finally, from the point of view of the spastic patient in general, the most valuable result of this work is not the variable amount of improvement in the 5 or 10 per cent that may come to operation, but rather what we may term a by-product. It is heartless to drive these patients into the hands of charlatans with the curt prognosis "hopeless," for we have had recalled to us, and emphasized, the distinct improvement that may be obtained in the large proportion of cases by tried and proved orthopedic measures and by muscle training and reeducation.

Dr. Charles S. Venable, San Antonio, Texas: Most certainly all of the weight of evidence from the anatomic, physiologic and histologic standpoint is against sympathectomies. On the other hand, there must have been some clinical improvements or possibly some cures to have incited so much interest and so much research. I have lost some of my enthusiasm and possibly a little of my optimism in the ultimate curative end-results to be obtained by what one may speak of as broadcasting sympathectomies. But, on the other hand, when one has seen the entire relief from the severe pain in the painful stump which had previously been subjected to alcoholic injections or further resection, or when one has seen an atrophic ulcer which had been treated over a great number of years and in a great many ways heal and remain healed, one is encouraged, for lack of possibly something else to do, to repeat this procedure because nothing else is offered. In cases of Raynaud's disease, of which I have had five, the primary result is the prompt relief from pain and apparently a very prompt tendency, due to vasodilatation, of the ulcer to heal. In two of these cases the ulcers have healed and remained healed for varying lengths of time. One great advantage seems to be the possibility of amputation at a site of election rather than the necessarily high amputation we have had to practice heretofore. In cases of diabetic gangrene I have been able to do amputations below the knee with prompt stump healing, which I have done at a period of election, from ten to fifteen days after the sympathectomy. In one instance it was four days after the sympathectomy. I think that we should at least feel sufficient encouragement to go on with the investigation, and clinically I am afraid that I am going to be the culprit until our friends investigate us and either prove us so entirely wrong that all clinical evidence seems to go the other way, or agree and come along with us.

Dr. Samuel Clark Harvey, New Haven, Conn.: It is very apparent that there is no definite correlation between the anatomic and the physiologic findings that Dr. Ranson has presented, and the clinical results that have been obtained by the operative procedures so far employed, and particularly the operative procedure of Coffey and Brown. I should like to know more about the position of the sensory fibers in the sympathetic tract. Dr. Ranson has spoken of the physiologic and clinical evidence, which seems not at all complete. I do not know that necessarily the lack of pain and response to the ordinary forms of stimulation employed at operation in the sympathetic system rule out the afferent impulses. The histologic evidence should be given more definitely, and I should like Dr. Ranson to tell us the evidence that he has from the histologic standpoint as regards the sympathetic sensory tracts. It is very apparent that the procedure employed clinically, and undoubtedly with palliative success, is of considerable importance. As to the selection of cases, we should be conservative. I do not feel that those cases that are diagnosed as coronary thrombosis should be ruled out. There are instances in which the outcome is very problematic, and certainly these should not be subjected to a prolonged and severe operative procedure under general anesthesia. As to the choice of operation, the less severe procedure should be employed first. The operation of Coffey and Brown, avulsion of the superior sympathetic ganglion or the division of the superior cardiac nerve and of the sympathetic trunk, is a relatively easy procedure which can be carried out perfectly well under local anesthesia, and as a tentative attack should be employed in each instance. Dr. Cutler did not lay sufficiently great emphasis on the fact that certain embarrassing sequelae may occur in any type of sympathectomy, the most embarrassing being the curious form of paresthesia analogous to or resembling Sluder's neuralgia. This may be very bothersome. Without doubt this operation has produced some results, perhaps not curative but certainly palliative. It is a purely empiric procedure, for the moment, not based on sound anatomic or physiologic reasoning. It is an experimental procedure on man, and such procedures on man should be carried out by those who are so situated as to make them scientific experiments. I do not think that the procedure is yet so sufficiently standardized as to justify employing it as a common therapeutic procedure. Dr. Cutler's paper exemplifies the study and care in the follow-up of the cases that is necessary, and these should be employed by any one who carries out this operative technic.

DR. WALTER B. COFFEY, San Francisco: Five years ago I severed the superior cardiac nerve and the main branch of the sympathetic in a patient suffering from frequent attacks of angina. Physiologists claimed that there were no fibers of sensation as high as the superior ganglion. The fact remains, however, that the eight or ten attacks a day in my case ceased. This operation has accomplished all that any of the numerous procedures more complicated and dangerous have done with equally less disturbance and less mortality, for attacks have recurred after unilateral and bilateral resection of the stellate ganglion. I have now operated in about thirty-five cases with encouraging results. Four times I had to resect on both sides. I cannot emphasize too strongly that surgeons should not attempt the procedure without the advice of good clinicians. No patient on whom I have operated has died of an attack of angina. The few deaths were from an underlying organic lesion. I have experimented on animals and done many dissections. My assistant at that time, Dr. John Humber, now assistant professor of anatomy at Tulane, has continued the dissections, using a technic, tried at operation by me, of inflating the ganglion. Such inflation spreads out through the various branches and fibers connected with the ganglion. The dissections show connections and collaterals not previously demonstrated. In some cases, we found the superior ganglion high up in the angle close to the jugular foramen, and in many instances I severed the upper pole of the ganglion. This would leave the carotid and jugular branches with its collaterals to the carotid plexus and tympanic plexus. It may be the explanation why we get pain in some of these cases due to impulses through collaterals. The tympanic plexus is the most important relay station in the sympathetic system. I am quite certain that where these two branches from the upper pole, that is, the internal carotid and jugular, were severed favorable results were obtained. In a severe case of angina, the upper sympathetic system was thoroughly inflated with triple distilled water. The angina attacks disappeared, but a remarkable incident occurred on the night of the operation. The patient developed Cheyne-Stokes respiration. I could account for this only through the spreading of the fluid through a branch (which I frequently find) from the superior ganglion to the phrenic to the vagus through the connecting branches.

DR. ALEXANDER LAMBERT, New York: Sympathectomy by several different operations has been successful for the relief of anginal pain, but the same surgical procedure in one man has not relieved the pain in another. The variation in man of the pathways of the sensory nerve fibers is as varied as are the opinions as to what is best to do. It is not known which are the usual sensory pathways in man. The opinions of Danielopolu and the French observers differ from those expressed by Dr. Ranson and Dr. Cutler. The operation of sympathectomy has a low death rate, but when the stellate ganglion is removed, there is a distinctly greater death rate from the immediate effects on the patient than in any of the other operations. If this stellate ganglion is removed, about one fifth of the patients die of acute edema of the lungs soon afterward. The success of the various operations may be due, *not to cutting of the sensory fibers, but to breaking* up of the reflex arc, and a prevention of excessive stimulation of the vasoconstrictor reflexes. All this doubt as to what may be the result of any given operation of sympathectomy emphasizes the wisdom of trying a procedure, previous to operation, which stops the pain where it expresses itself on the body. All sensory nerves coming from the viscera go through some spinal nerve to the spinal cord by way of the white rami; these white rami occur only from the first dorsal to the fourth lumbar; therefore, when pain comes from the heart, it goes into the spinal cord through one of these nerves. All sensory nerves go through the posterior root ganglion of these spinal nerves, and this posterior root ganglion can be reached and the sensation of pain can be blocked off in that root ganglion. This has been done in New York by Dr. George Swetlow with marked success. It is not a difficult operation, it does block off the pain where it shows itself in the body segment, and it is the relief of pain that the patient seeks. It is asserted that the pain of angina is a warning, and a protective sensation: It is well to remember that the pain is the other man's pain, not yours, and he should be the one to decide whether or not it should be removed, especially since Bayliss has shown that through the sensory nerves the vasoconstrictor reflexes cause the danger in the angina. If these vasomotor reflexes can be cut off with the cessation of pain, the advantage is vastly greater than the mere relief of the pain. Most patients in whom the pain has been relieved by sympathectomy have shown distinctly an increased ability for exertion without excessive cardiac disturbance, which they did not possess previous to operation. Thrombosis of the coronaries, or coronary disease, *does produce pain, and not all anginal pain comes from the* aorta alone. It is also a curious fact that 25 per cent of those suffering from coronary disease have their expression of it in the epigastrium in the nerves that come out from the second to the ninth dorsal vertebrae running into the plexuses on the esophagus, lungs and heart. One cannot by any sympathectomy stop this expression of pain. In the epigastric pain, therefore, one is reduced to the necessity of blocking it, if one desires to help it. In only 10 per cent of patients suffering from coronary disease does the pain go down the arm and sympathectomy have a chance to help.

DR. ARTHUR STEINDLER, Iowa City: This symposium is a general attempt to break down some of the claims that have been made by Royle and Hunter, and if it is, a thorough job has been done. I have been very much impressed with what I have heard today, but when we heard Royle and Hunter, we were likewise deeply moved by the thoroughness and earnestness of their work. I feel that while this investigation into their work is going on, it is proper to investigate the investigation. From the physiologic point of view, the matter stands as it did some time ago, namely, that it is acknowledged that the sympathetic nervous system has a direct influence on the innervation of the peripheral or *skeletal muscles*; but the question of how this innervation is arranged is still unanswered. I regret that the experiments have not been extended to the fowl and to the seagull, in which spastic tone is especially noticeable and spastic tone is a definite function and not an obstacle, as it is in man. I believe it the strongest point in the physiologic investigations of Hunter that special sympathetic control was to be found in these birds that soar and that have to keep their wings in a special state of contracture for an unbelievably long time. When it comes to the clinical evidence, it seems to me that the cases in which we have succeeded must be explained first before we can dispose of sympathetic innervation as a physiologic factor. I am greatly impressed with what I have heard today, but it seems to me that there are still holes in both presentations of the case, negative and positive. Royle and Hunter are still insisting on the efficacy of the method on the physiologic grounds for which they have accepted the findings of Langelaan and the histologic findings of Boeke.

Dr. W. B. Carrell, Dallas, Texas: Stimulated by the work of Hunter and Royle, we were encouraged to do a series of ramisections in Little's disease during 1925. Twenty-five of these were lumbar and ten cervical. In all lumbar cases definite hyperemia followed within a few hours, with from 1 to 2 degrees elevation of surface temperature and the sensation of warmth persisted in all cases. This was very noticeable in children reexamined months later, during cold weather, when the foot and leg on the operated side was distinctly warmer than on the other, but without any elevation of temperature. The improvement in the function has not been marked, but in fifteen cases the gait was improved to the extent of more ease in flexing and bending the knee and walking with less rigidity. The parents and patients themselves were pleased with the improvement and motion pictures show increased motion at the knee after the operation. We did not have any appreciable change in the reflexes, the amplitude of the knee jerk was the same and the *sustained action was as great as before operation.* The cervical cases have not shown any appreciable improvement. We did not get the early hyperemia as pronounced, which has perhaps resulted from less thorough operative technic.

Dr. S. W. Ranson, St. Louis: Some one raised the question as to the proof that large fibers in the sympathetic system are sensory. That proof was offered more than twenty years ago by Edgeworth, and his findings have been confirmed by me. If the roots of spinal nerves are cut proximal to the spinal ganglions, all the motor fibers degenerate; the sensory fibers remain. If, after section of the roots of the thoracic nerves, one studies the corresponding white rami, one finds that these large fibers remain because their cells of origin are in the sensory ganglion. One clear evidence that the pain fibers from the heart do not pass upward through the cervical sympathetic trunk to the superior cervical sympathetic ganglion is the fact that in a considerable number of cases characteristic anginal pain has recurred after removal of the superior cervical sympathetic ganglion. In one such case, after removal of the left superior cervical sympathetic ganglion, pain of typical anginal character recurred, and in the course of months it became even worse than before, as a result of the progress of syphilitic aortitis. It seemed that it would be difficult to remove the lower part of the cervical sympathetic trunk and the first thoracic ganglion. So Dr. Sachs cut the sensory roots of the first four thoracic nerves of the left side approximately three weeks ago, and since that time the patient has been absolutely free from pain. That, I think, answers the question that was raised by Dr. Lambert in regard to the variations in sensory paths, showing that after all if the dorsal roots of the first three or four thoracic nerves are cut on the left side, the pain disappears. Dr. Cutler mentioned a case in which, after bilateral removal of the stellate ganglions, pain persisted. I should like to know whether, perchance, that pain is not the collar pain round the upper part of the neck over the jaw and shooting up on the side of the head which many years ago was attributed by Head to a reference from the vagus into the distribution of the upper cervical and trigeminal nerves.

Dr. Alexander Forbes, Boston: It has been said that it was "up to" physiology to solve the problem of tonus. I have found no convincing evidence that tonus is anything more than a name, by which I mean that tonus is not in any fundamental respect different from any other contraction. If one stimulates a frog's muscle with a single, instantaneous stimulus, one gets a brief contractile twitch lasting about a tenth of a second. If one stimulates the muscle repeatedly with stimuli at a rate of more than twenty a second, one gets sustained contraction, but there is no fundamental difference between those contractions; in the latter case the disturbances follow one another so rapidly that contraction is mechanically sustained. I very much doubt if skeletal muscle, except under peculiar conditions, such as fatigue, producing increase in acidity, has two kinds of contraction; that is, whether the sustained contraction we call tonus is fundamentally different from the briefer contractions, any more than the tetanized muscle differs fundamentally in its behavior from the muscle subjected to a single stimulus. As to the work of Langelaan, in which he attempted to show a fundamental distinction between plasticity and contractility in muscle, I have examined his work carefully and can find no logic in it whatever. He definitely misquotes the work of Lucas and misinterprets some of his observations. He bases his distinction apparently on the difference between a twitch produced by a single brief stimulus and a reflex contraction of gradual onset; but the reflex contraction, as far as the evidence was concerned, was presumably built up of individual responses of the same fundamental character as that appearing in the twitch. Sherrington, Liddell and Fulton recently reported a large volume of very important work showing how the impulses of muscle sense serve to produce reflexly sustained muscular contraction. They are of the most profound importance. I should have mentioned, perhaps, a possible explanation for the effects of sympathectomy. If the disturbance of circulation affects the intramuscular receptors, there may be some modification of their function, and an alteration of the afferent impulses arising therefrom with a consequent change in reflex effect. I do not think we are justified in assuming, yet, that there is a plastic tonus or that tonus is fundamentally different in any way from other sustained contraction of voluntary or reflex origin.

Dr. Loyal Davis, Chicago: Many new methods of treatment for spasticities of the extremities have been advocated. With reference to the experimental work of Hunter done on fowls, it must be borne in mind that it is very difficult to perform a ramisectomy on birds without seriously injuring the anterior motor roots of the animal's plexus. Of course, by such trauma one produces an immediate flaccidity in the wing of the same side. This has been the almost universal objection to this particular experimental work, and one can easily understand such difficulties if one attempts to perform this operation. The extensive posterior root sections practiced by Trendelenburg and his careful controls and subsequent records would tend to support the view that some other factor than posterior root section is operative in producing the drooping of the wing shown in Hunter's animals. Trendelenburg concluded that somatic afferent and sympathetic denervation of a single wing did not produce drooping or a defect in voluntary and reflex movements. We have operated on cats in these experiments. If this hypothesis is fundamentally sound, then we should get results regardless of the animal operated on. Unless we can prove experimentally that we have a basis for this operation, then we have no surgical right to subject these patients to such an operation. In other words, we are operating in an empiric manner. Another point with which all are familiar is: Any new treatment which orthopedic surgeons, general surgeons or anybody else has instituted for the treatment of spastic diseases of the extremities has always succeeded early in the history of that treatment.

Dr. Raymond W. McNealy, Chicago: I have only one thought in mind in discussion, and that is to bear witness to the fact that there have been reactions and improvements that have resulted in a number of cases in which operation was done by perivascular sympathectomy. The point I wish to make is that these results cannot be directly attributed to the essential part of the operation; that is, the stripping of the perivascular sheath. Comparable results have been obtained by section of the sensory nerve of the area, by subcutaneous injection of foreign protein material. So far as the operation itself goes, we must have more proof that it in itself is advisable.

Dr. Elliott C. Cutler, Cleveland: It has been most encouraging to note the great appreciation of the physiologic processes involved in the foregoing discussions. I should like to emphasize that the surgical treatment of angina pectoris is still in the experimental phase. The suggesion of Dr. Coffey that infiltration of the nervous structures during operation renders them more easily visible is of benefit to the surgeon. I cannot agree, however, with his reasoning that in the operation of removal of the superior sympathetic ganglion they interrupt the nervous arc on the efferent side, for stimulation at this point does not result in the signs and symptoms of angina pectoris. Dr. Lambert's proposal that alcohol be injected into the root ganglions, as advocated by others, seems unsafe; and, since it is a blind procedure, and one cannot be sure just what is affected by the injection, it should not be used during the experimental stage of the investigation of this matter. I would further emphasize the embarrassing sequelae that may follow operation in this field. Horner's syndrome is a small matter compared with the bizarre pain that may appear in the jaw, the neck or the chest. These pains do not seem to be explained by interfering with sensory nerves on the operative field but may result from circulatory changes due to interference with the vasoconstrictor apparatus or from neuronic degeneration in the sympathetic nerves extending back into sensory nerve areas. Dr. Ranson has questioned the return of pain on the right side in one of our patients submitted to a bilateral Jonnesco operation. I feel that this may be due to stimuli reaching the cord through the second dorsal ganglion.

Clinical Notes, Suggestions, and New Instruments

DOUBLE TUBAL PREGNANCY WITH RUPTURE OF BOTH TUBES

FRED E. CLOW, M.D., WOLFEBORO, N. H.

This case is reported because of two unusual features: the simultaneous occurrence of pregnancy in the two fallopian tubes, and rupture of both tubes with a considerable interval separating the two accidents.

H. U., an unmarried woman, aged 41, was taken suddenly ill, June 26, with severe cutting pain in the right lower quadrant of the abdomen, with faintness and nausea. The pain occurred while lifting a heavy chair. The physician who was called did little, evidently, beyond giving a hypodermic injection of a narcotic. The patient stayed in bed for three days and then returned to work. She noticed only some tenderness of the abdomen and general muscular weakness. July 10, a similar seizure occurred with pain in the left lower quadrant of the abdomen, faintness and vomiting. There was a slight vaginal discharge of dark blood. The same physician was consulted, but no treatment was prescribed save rest in bed and an ice bag to the abdomen.

July 30, the patient was brought to the hospital. She admitted that there had been no menstrual period for two months preceding the first attack of pain. Examination showed moderate distention of the abdomen, with dulness in both flanks and throughout the lower part of the abdomen. There was moderate distention and general tenderness and rigidity of the whole abdomen. Vaginal examination showed a soft, tender uterus, a boggy mass filling the pelvis, and a foul, dark discharge from the cervix. The temperature was 100.8 F. (39.8 C.); pulse, 108. The patient looked ill.

The abdomen was opened under ether anesthesia. The pelvis was filled with organizing blood clots. The right tube, ovary and appendix were glued together in a mass of fresh adhesions. The distal third of the tube was distended, with an opening 2 cm. long filled with blood clot and organizing material. The left tube was enlarged and, with the ovary, was similarly adherent to the uterus, bladder and small intestine. The left tube was removed, the abdomen cleared of clots, and the wound closed with a cigaret drain in each side of the pelvis.

Examination of the specimens showed, in the right tube, a distention of the distal half, with an obvious tear, filled with blood clot. The left tube was distended throughout. In the middle third was a tear 2 cm. long with a blood clot protruding through it. No trace of either fetus could be found.

The patient developed bronchopneumonia and died on the eighth day.

OCCUPATIONAL DERMATITIS FROM WOOD TURPENTINE*

CAREY P. McCORD, M.D., CINCINNATI

The best grade of turpentine is obtained by tapping the living pine trees collecting the resins that exude, and refining them. The turpentine so derived is "gum spirits of turpentine." This method is wasteful of timber, and its use is rapidly diminishing. Lumbering operations afford every year a vast lot of waste wood. Attempts are being made to produce a high grade of turpentine from these rejected woods and uprooted ancient stumps through steam distillation and destructive distillation methods.

The Naval Stores Act of 1924, recognizes these grades of turpentine:

"Gum spirits of turpentine," which means spirits of turpentine made from gum (oleoresin) from a living tree.

"Steam distilled wood turpentine," which is wood turpentine distilled with steam from the oleoresin within or extracted from the wood.

"Destructively distilled wood turpentine," wood turpentine obtained in the destructive distillation of the wood.

"Wood turpentine," which includes steam distilled wood turpentine and destructively distilled wood turpentine.

Wood turpentines in many respects are satisfactory for industrial uses. The costs of steam distilled wood turpentine and destructively distilled turpentine are lower than for gum spirits of turpentine. However, these new process turpentines are proving far more irritating to the skins of exposed workers; the destructively distilled is probably more irritating than the steam distilled wood turpentine.

In the distilling process, the liquid condensate flowing from the still, from which wood turpentine is subsequently derived, is termed "crude pyroligneous liquor.[1] This is a heterogeneous mixture of chemicals which includes acetic acid, formic acid, methyl (wood) alcohol, formaldehyde, acetaldehyde, acetone, acrolein, methylamine, furfuraldehyde, phenols, benzene, pyridine, isoprene, methyl-ethyl-ketone and some others. Many of these constituents present with the terpenes will readily be recognized as well known skin irritants. In the pyroligneous acid (one fraction of the crude pyroligneous liquor) the content of certain irritants is, approximately: acetic acid, 4 per cent; methyl alcohol, from 2 to 4 per cent; formic acid, 1 per cent; formaldehyde, from 1 to 2 per cent; furfuraldehyde, 1 per cent; methal acetate, from 2 to 4 per cent. The constituents of wood turpentine, of course, vary as to nature and percentage with every lot produced. With such an array of possible irritants, the occurrence of dermatitis among exposed workers is almost inescapable.

At the present time two outbreaks of wood turpentine dermatitis are under my observation. The exposed workmen are in unrelated industries, but utilize the same grade of distilled turpentine. In one factory about fifty workers are exposed to naphtha or to wood turpentine. For a period of twelve years, ending a few months ago, gum spirits of turpentine was employed as the paint solvent. During this period only about three cases of occupational skin disease developed every year. Recently wood turpentine was substituted for the grade formerly in use. During the last two months, thirty-five cases of dermatitis have been reported by the foreman. At this time ten cases are under my observation in this factory. The skin lesions exhibited in these cases have no specific characteristics. They resemble the dermatitis frequently seen from a great variety of chemicals, such as naphtha and benzene.

In this situation, immediate betterment may be had by returning to the use of gum turpentine. This measure promises only temporary relief, for the method by which gum turpentine is now obtained is doomed to industrial extinction. Freedom from this hazard will come about when in the distillation process careful fractionization is provided, in order that these numerous irritants may be kept apart from the relatively harmless terpene oils.

AN EVER-READY SUTURER

Myer M. Marbel, M.D., Chicago

The device here described and illustrated was developed with the idea of furnishing the physician a convenient, sterile and ever-ready combination for sewing up wounds. It embodies features of simplicity, efficiency and convenience that will afford increased skill and greater speed (from four to six stitches per minute), with better asepsis and less chance for contamination on the part of the operator. In caring for emergency wounds away from office or hospital, it lends itself to a high degree of convenience and safety.

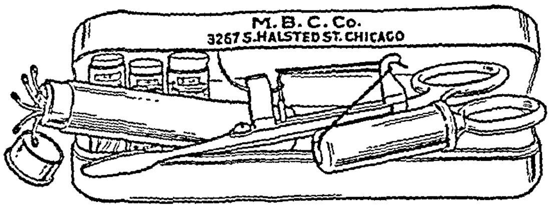

Fig. 1.—Suturer in case.

To one arm of the needle holder-hemostat is attached a tank holding 300 inches of suture material; the suture is immersed in alcohol and contained within a removable glass vial. To the second arm of the needle holder-hemostat is attached a threader with two vises that will automatically thread the needle and then anchor the suture material to the needle's eye. On and below the grip-jaws of the same needle holder-hemostat are scissors blades for cutting off the ends of each stitch made, as well as the anchored knot on the needle.

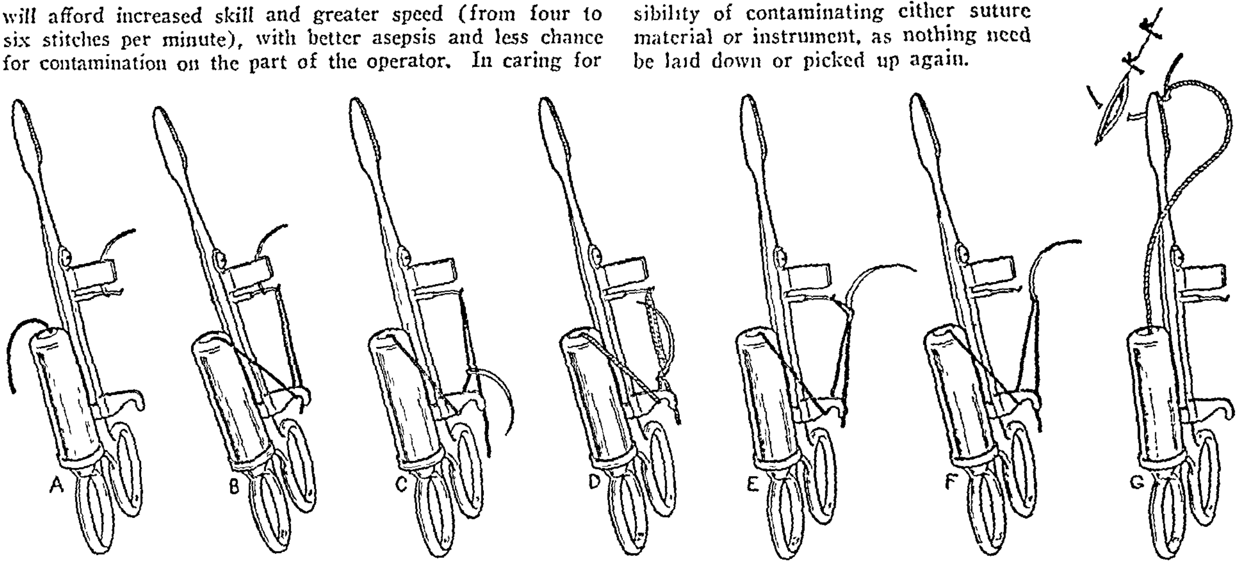

Fig. 2.—Manipulation: *A*, needle on hook threader, *B*, needle and catgut on hook threader; *C*, needle threaded; *D*, threaded needle sinking between lines for anchoring; *E*, needle half anchored; *F*, needle anchored; *G*, suturer in use

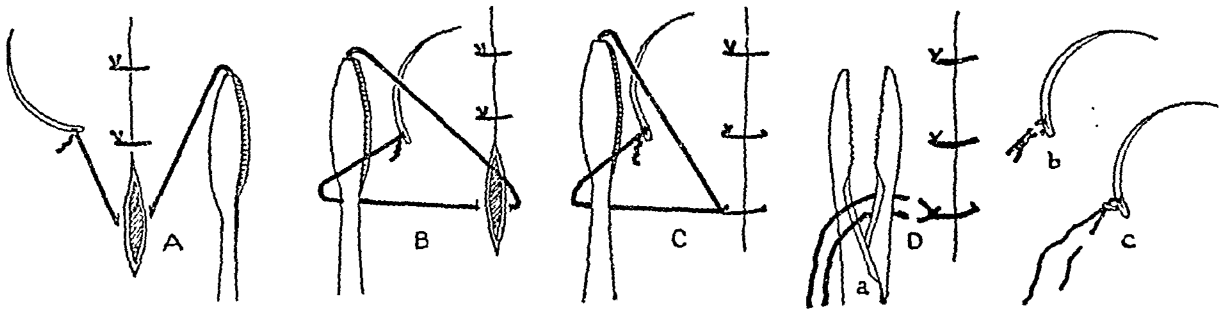

Fig. 3.—Further manipulation: *A*, two sides of catgut forming an angle (needle kept in left hand and instrument in right hand); *B*, knot (first half) made on triangle (needle goes through center of a triangle formed by catgut from wound as its apex and instrument as its base); *C*, knot (second half) closed on triangle; *D*, with scissors within suturer, ends (*a*) are cut off at wound; knot anchored (*b*) at needle's eye cut off and needle rethreaded for next stitch; *c*, too long end cut off before stitching is started.

These three additions to the ordinary needle holder-hemostat form a one unit instrument that enables the operator to do in an automatic manner, with fine technic, five or six stitches per minute.

The manipulation is as follows:

The needle is threaded.

The needle is anchored.

The knot on the triangle is made. (The needle goes through the center of a triangle formed by two sides of the suture material from the wound as its apex and the instrument as the base.)

Both ends of the stitch made are cut off.

The knot is cut off; the needle is anchored and rethreaded for the next stitch.

As the device is held in the right hand constantly with its tank side over the thumb, and the left hand is assisting, the operator is thus equipped for any number of stitches with a minimum loss of blood in profusely bleeding wounds. There is little possibility of contaminating either suture material or instrument, as nothing need be laid down or picked up again.

The *grip-jaws* are concave in the center and hold any curved needle at two points firmly and without danger of breaking it.

The *suture tank* is reloaded by unscrewing it, pushing out the empty bottle, and inserting a new fresh bottle.

The device is sterilized as a unit in its tightly closed metal container, either in dry heat or by boiling.

This device has given excellent satisfaction for skin stitches, circumcisions, repairs of the perineum in the homes of the poor, and all other types of suturing in which it has been used.

3267 South Halsted Street.

APHONIA FROM GOITER*

JOHN WILLIAM SHUMAN, M.D., LOS ANGELES

Loss of voice is a rare condition when it is caused by pressure of the thyroid gland. R. C. Coffey[1] does not remember having had a case of aphonia which was relieved by the removal of a goiter.

G. W. Crile[1] says: "About 4 per cent of our cases show a unilateral paralysis and often present some difficulty in speech but usually are thoroughly compensated. With the exception of malignant cases I have never had a case with complete loss of voice. The functional side of such a case must of course, be considered. A laryngoscopic examination would clear up this point."

E. S. Judd[1] cannot recall a case of this sort except one or two in which there was a hysterical aphonia which was relieved by operation; these, however, showed no definite paralysis of the cords on laryngoscopic examination.

REPORT OF CASE

A white man, aged 30, married, was admitted, May 28, 1925, to the service of the throat clinic with the complaint, loss of voice, of two months' duration, which had come on gradually.

The patient continued to lose weight until July 2, when, during consultation, a definitely enlarged thyroid was found and given as a cause for the aphonia.

The patient was nervous; he had tachycardia; the palpebral fissures were wide; the upper lids lagged; the pupils were dilated; the skin of the face and neck was cyanotic; effort increased the symptoms; when he attempted to speak, the superficial jugulars were visibly distended and the base of the neck ballooned, most markedly on the right side. Roentgen-ray findings by Dr. R. C. Shawhan were: increased density in the soft tissues in the thyroid region; lower poles on a line with the third dorsal vertebra. Major Frisbee found in the chest a dilatation of a bronchus on the right side, evidently due to obstruction and pressure from without.

July 14, Dr. Merrill, the throat consultant, found general congestion of the larynx and trachea; the cords moved well, and the aperture was symmetrical in all positions. The cords gave evidence of some thickening. July 28, he reported marked subglottic inflammation, with thickening of the mucosa extending into the trachea—a definite tracheitis.

September 17, James A. Mattison removed both lobes of the thyroid, and the isthmus were resected, sufficient thyroid being left next the trachea to take care of physiologic function. The capsule of the thyroid was firmly adherent to the gland, and the two lobes extended around the trachea posteriorly; with much difficulty the capsule was freed and the lobes were delivered. Dr Williams, the pathologist, reported "hypertrophy of the stroma, exophthalmic goiter," on the resected tissue.

The patient recovered his voice during the operation. His convalescence was uneventful and he was discharged, September 29, stating that he felt fine. He appeared well. His voice was clear, with good tone. He had no difficulty in breathing or deglutition. He had gained 12 pounds (5.4 Kg.), and his general condition had improved markedly.

Nature of Present-Day Health Movements.—It is clear that the policy of present-day health movements is increasingly directed to educational methods. It is with these objects that sanitary inspectors, welfare workers or health visitors are employed, that clinics are established and that industrial employers safeguard their employees. "Health Weeks," "Baby Weeks," lectures, literature, models, exhibitions, all help to create an educated public opinion, and we all of us appreciate the services of the statesman, distinguished cleric, or popular actor, or actress who is good enough, on occasion, to convey to the public the homely truths, which are so much more arresting when coming through these channels rather than through the usual ones.—Hope, E. W.: *Proc. Roy. Soc. Med.* **19**:29 (March) 1926.

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS*

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(Continued from page 1911)

GENITO-URINARY MEDICATION

URETHRAL MEDICATION

The administration forms for medication of the urethra in descending order of importance are: (1) lotions, (2) urethral suppositories, and (3) ointments.

Urethral Lotions.—These may be given by injection, instillation or irrigation. The mucous membranes of the urethra and of the bladder being highly sensitive, only mild solutions, such as could be tolerated in the eye, should be used on these membranes. Solutions should never be strong enough to cause more than temporary stinging or pain. The lotions should always be employed warm, as in acute cases, at least, cold solutions are liable to produce irritation, and heat increases the activity of all chemical agents. What is perhaps not sufficiently realized is the great absorbing power of the urethra, and that the absorbing power of the posterior urethra is even greater than that of the anterior urethra. This is in marked contrast to the very poor absorption from the urinary bladder, which is all the more interesting as the upper portion of the urinary tract, the ureter and the renal pelvis are again highly absorptive. These facts, which were established experimentally most especially by Macht,[67] and also by Magoun,[68] are of practical importance, especially in connection with the application of local anesthetics to the urethra, poisoning from which has been repeatedly observed clinically. Rather surprising is the great absorptive power of the prepuce, which must be borne in mind when local anesthetics are applied to it for surgical purposes.

Before using a urethral lotion the patient should always urinate, as the urine cleanses the mucous membrane of exudate and permits the remedy to come into more direct contact with the diseased part. It also lessens the liability of transportation of infectious material into the upper portions of the urethra.

Urethral Injections.—For self-administration of injections into the anterior urethra, the patient should be sitting well forward on the edge of a chair. If it is very important to obviate the possibility of the fluid entering the bladder, the patient should sit on a folded towel, which will help to cut off the deep urethra; usually, however, the cut-off muscle of the urethra suffices to secure this result. The penis should be held between the thumb and the fingers of the left hand. The meatus is opened by gentle pressure; the syringe (from 10 to 15 cc. capacity with blunt, conical tip) is introduced; and, while the thumb and index finger of the left hand make water-tight closure of the urethral orifice with the tip of the syringe, its contents are gently discharged into the urethra. At first only about 4 cc. should be injected at a time. In the later stages of the disease from 12 to 15 cc. may be introduced. Any air present in the syringe should be expelled, before injecting, by pressing on the piston while the tip of the syringe is elevated. As the first injection is chiefly for the purpose of cleansing, it may be permitted to escape immediately. After the second and third injections, the syringe is laid aside; and, while the left hand maintains closure of the meatus, the right hand attempts by gentle stroking pressure over the under side of the penis to distribute the solution to all portions of the canal. In this manner, the injection is retained for five minutes, when another syringeful may be injected and retained for an even longer period. These treatments are repeated in acute cases from three to six times daily, with diminution of the discharge morning and evening only. It must be remembered that sometimes the continued use of injections maintains a discharge, which may persist for a week after their discontinuance.

Should a sedative injection be desired, a 0.5 per cent solution of cocaine hydrochloride in equal parts of mucilage of acacia and water might be useful. For local anesthesia of the urethra, cocaine should not be used, as it is incalculably toxic. Though procaine hydrochloride U. S. P. is relatively inefficient when applied to intact mucous membrane, it is comparatively safe. Complete urethral anesthesia cannot be expected from it. One injects into the urethra from 8 to 15 cc. of a 2 per cent procaine solution, to which 2 per cent of sodium bicarbonate might well be added, as it intensifies the action of the alkaloid, and from 3 to 5 drops of the 1:1,000 solution of epinephrine. The latter is added just before use, as the mixture decomposes on standing. As the solution should remain in the urethra from fifteen to thirty minutes—the longer the better—a clamp for the penis (such as Stockmann's) is desirable. To lessen the sensitiveness of the deep urethra, an injection of 15 cc. of the solution is forced into the urethra five minutes after the first one has been applied. This will enter the membranous portion of the urethra and should be permitted to act for twenty or twenty-five minutes. As procaine is a hydrochloride and the chloride ions would precipitate and inactivate a succeeding silver nitrate instillation, a procaine nitrate solution (5 per cent) should be employed instead, the alkali should be omitted, and the epinephrine, which is likewise used as hydrochloride, dispensed with for the same reason. To anesthetize the deep urethra completely, infiltration of the tissue surrounding the prostate by from 75 to 100 cc. of 0.5 per cent procaine solution is required. A 4 inch needle is used for the purpose. For anesthesia of the bladder, instillation of anesthetic solutions is entirely ineffective for reasons now well understood; and parasacral injection must be employed.

Antiseptic lotions must never be employed with the idea of eradicating an established infection. This is impossible. All gonorrhea heals, if it heals at all, through the natural reaction of the infected organism. This reaction can be favored by our therapeutic means; and we must be ever careful not to hinder it. The more acute the inflammation, the milder should be the therapy. In acute gonorrhea, injections of mild antiseptics without the use of a catheter are chiefly of value for cleansing purposes. Regarding irrigations at this stage, opinion is divided. In the chronic stage, astringent injections, irrigations, and instillations combined, if required, with dilation are undoubted means of expediting a cure. It is an important principle to treat all the affected portions simultaneously. Thus, to treat the anterior urethra only, when the posterior urethra is also affected, leads to so-called relapses.

The most popular antiseptics for injection into the urethra in case of gonorrhea are silver compounds, because silver is believed to be specifically gonococcidal. The nonastringent silver compounds are preferred in the early stages, while gonococci are present, as the discharge obviously helps in the elimination of the invading gonococci. Not a checking of the discharge, but of the proliferation of the gonococci, is our aim. The more profuse the discharge, the milder should be the injections, and vice versa. Mild silver protein, in recently prepared solution of 2, 5 and even 10 per cent strength, and strong silver protein in 0.25, 0.5, 0.75 and rarely 1 per cent strength are favorite agents for this purpose. The milder remedy and the lower concentration are employed at first; and the concentration, strength of agent, and duration and retention of the injection are gradually increased as the condition becomes less acute.

To use powerful germicidal, disinfectant remedies in the treatment of this or other infected membrane is veritable folly: for the micro-organisms that have invaded a membrane cannot be killed, while the membrane will surely be injured. Better to leave the membrane in peace than to treat it *cum furore.* Only for prophylactic or abortive treatment are germicidal applications admissible. It is true, they irritate; but, if they succeed in exterminating the pathogenic organisms while they are still on or in the surface, they may check the further development of the disease. Thus, 10 per cent strong silver protein in glycerin solution, instilled into the fossa navicularis by means of a medicine dropper so as to penetrate the anterior urethra about half an inch, is said to be an efficient prophylactic of gonorrhea, provided it is employed early enough after the [illegible]. As a preventive against [illegible] ointment" of the National Formulary, the ointment of mild mercurous chloride (30 per cent), should be used at the same time.

Astringents—from 0.2 to 1 per cent zinc sulphate, or 1:2,000 silver nitrate—should not be employed until the later stages after the gonococci have disappeared from the discharge because, though astringents promptly lessen the discharge, they create a false sense of success and security; for, as soon as the treatment is stopped, the discharge is liable to recur. Their action is too superficial to destroy the gonococci that have invaded the tissue; and, by checking the discharge that might have carried them away, they may actually prolong the disease and even invite complicating deep invasion. Perhaps the mildest of the astringent lotions is Ricard's injection, a "shake mixture" compounded with 0.5 per cent of zinc sulphate and 1 per cent of lead acetate, with a little mucilage of acacia, to favor suspension, in rose water. To this, 2 per cent each of tincture of gambir and of tincture of opium were added in the original formula. This mixture is chemically incompatible but is entirely admissible clinically, as the finely precipitated lead sulphate is believed to exert a beneficial protective influence on the inflamed membrane. There is a slight excess of lead acetate.

Instillations.—Instillations are employed to medicate limited portions of the urethra with small quantities of rather strong solutions. They must not be used in acute cases or in the presence of acute complications of chronic cases. They are, on the other hand, very useful in the chronic stage, most especially in chronic posterior urethritis. While the urethral injections described above are generally entrusted to the patient for self-administration, instillation of medicaments into the posterior urethra requires the aseptic technic of the physician. When the three-glass test or the symptoms, such as recrudescence of the discharge, and burning pain in the perineum, indicate involvement of the deep urethra, these instillations are administered by means of a Guyon or analogous syringe, or a catheter is passed down to the posterior urethra (from 5½ to 6 inches), but not far enough to enter the bladder. Rather strong solutions are employed, generally from 1 to 2 per cent solutions of silver nitrate, with the intention of inducing a curative hyperemia; indeed, of substituting an acute inflammation with a tendency to heal for the chronic inflammation without this tendency. From 5 to 20 drops is instilled if the prostatic urethra alone is to be treated; from 5 to 10 cc., if the base of the bladder—which is also usually affected—is to be medicated likewise. In the latter case, it is well to leave a little urine in the bladder to protect the more sensitive fundus. In removing the catheter, care must be taken to avoid having any of the solution drip along the anterior urethra. This is done by slightly withdrawing the piston of the syringe before removing the catheter. There is generally considerable burning on urination, and there may be increase of the discharge during the first twenty-four hours following an instillation. If the reaction is severe, rest in bed, an opium suppository, and heat to the perineum should be employed. These instillations do not have to be repeated oftener than twice a week. The next instillation should certainly not be given until all irritation produced by the previous instillation has completely disappeared.

Such instillations are also useful to lessen the congestion of the deep urethra, which is a frequent cause of irritable weakness of the sexual functions, resulting in deficient erection and premature ejaculation. They also, of course, have a psychic value in these cases. Instillations into the anterior urethra are advantageously employed in those cases of chronic gonorrhea in which there is found localized tenderness and induration on passage of a bulbous bougie. Such areas not only maintain a chronic discharge, but are liable to be the beginning of strictures.

Irrigation.—Urethral irrigations, though employed according to Janet's recommendation within the first thirty-six hours of an attack of gonorrhea, are probably best avoided in fresh cases of gonorrhea. They irritate too much and are liable to lead to posterior urethritis, prostatitis and epididymitis. When, however, the discharge continues to carry gonococci, and when these parts are affected, they may be used with advantage. They should always be administered by the physician. The apparatus consists of an irrigating reservoir raised not more than 4 feet, less if the pressure produces pain; a Valentine or Chetwood two-way blunt tip glass urethral nozzle, connected by means of 8 feet of rubber tubing to the irrigator, and another shorter piece of rubber tubing leading from the outflow tube to the waste-pail. A rubber apron with a hole for the penis protects the clothing of the patient, who may stand or be seated on the edge of a chair for irrigation of the anterior urethra, but should be lying down for posterior irrigation. The glans penis and the lips of the meatus should be washed with soap and water, followed by 1 : 5,000 mercuric chloride solution. A hot solution of potassium permanganate, from 0.25 : 1,000 to 1 : 1,000, is most commonly employed. The chief effect of this solution is not so much a destruction of the gonococcus as the production of a "serous reaction," a copious thin secretion which, it is asserted, clears the mucosa quite rapidly of gonococci. This, however, is not always the case; and, if gonococci persist, it is well to change after a while to silver nitrate, 1 : 12,000 to 1 : 8,000, or mercuric oxycyanide, 1 : 3,000. The latter is conveniently prepared by adding 30 cc. of a 1 per cent stock solution to 1 liter of hot water. The patient should, as usual, empty his bladder before the irrigation. The operator, holding the penis behind the glans between the thumb and forefinger of the left hand, and compressing the rubber inflow tube between the thumb and index finger of the right hand, inserts the nozzle into the meatus. He then releases the inflow tube, at the same time closing the outflow tube by means of his right little finger. As soon as the urethra is filled, the inflow tube is pinched and the outflow tube released. Thus, the urethra is alternately distended with solution and emptied, without removal of the nozzle. For irrigation of the deep urethra, the anterior urethra is irrigated as just described, and then a catheter is passed until the urine just escapes, when it is withdrawn about an inch, and from 100 to 350 cc. is gently injected through the posterior urethra into the bladder. The catheter having been then removed, the patient empties the bladder, thus passing the solution once more through both posterior and anterior urethra. These hot irrigations should be continued until the discharge is free from gonococci. In very resistant cases, irrigations should be combined with dilation.

Urethral Suppositories.—These little rods, pointed at one end, also known as medicated bougies, generally made of glycerogelatin, may be inserted into the urethra, where they melt, releasing their medication. They are made in two lengths: either 7 cm., weighing 1 Gm., or 14 cm. long, weighing 2 Gm. The agent remains in contact with the mucous membrane for quite a time, which may secure more thorough medication, but also produces greater irritation. Strong silver protein (5 per cent) bougies may be used in venereal prophylaxis. For treatment, 0.1 per cent silver nitrate, 1 per cent zinc sulphate, or 1 per cent resorcinol bougies are employed.

Ointments.—Ointments may be applied to the urethra by means of a sound smeared with the medicament; or else by having the ointment dispensed in a collapsible tube and introducing it into the canal by means of a small, soft rubber tube, as described in connection with rectal medication by ointment. On the whole, ointments do not yield better results and are more troublesome than bougies.

The bladder and urethra may be medicated in a very mild degree by the peroral administration of certain drugs that are freely eliminated in the urine. Of course, the degree of medication must of necessity be much less than when a remedy is applied locally, and the effect of the agent on the alimentary tract and system has to be reckoned with; but the constancy of the medicinal impression may counteract to a certain degree its feebleness.

GOITER PROPHYLAXIS IN NONGOITROUS AREAS

For the orderly progress of medicine, "novelties" of diagnosis and treatment should be investigated thoroughly as promptly as possible. This is true not merely because of the desirability of securing effective helps in practice at the earliest opportunity and of revealing deceptions or disappointments before false hopes are engendered; but also because careful investigation usually discloses the limitations of new procedures and sometimes points the way to their betterment. Illustrations of this may be found in the more recent histories of the use of arsphenamine, insulin, cholecystography and various antitoxic serums. The expectations of their early exploitation have not always been realized completely; yet this has led to improvements in technic and limitations of application that will in the long run render a more permanent and helpful contribution to the medical art.

The so-called thyroid or goiter surveys that have been initiated in various parts of the world during the last few years have disclosed an unexpected incidence of thyroid enlargement.[1] It is believed that the adolescent goiter or thyroid hyperplasia is a compensatory reaction arising in the course of a metabolic disturbance and immediately dependent on a relative or absolute deficiency of iodine. The efficacy of small doses of this element in preventing the expected incidence of such thyroid enlargements has been abundantly demonstrated. As an outcome, "goiter prophylaxis" has been instituted particularly among school children in many regions. It has also been attempted on a wholesale basis among larger groups of the population through the common use of iodized table salt or the treatment of potable water supplies with iodine. Of late, this procedure has provoked some protests,[2] owing to the alleged possibility of producing symptoms of hyperthyroidism in persons who do not require iodine medication.

According to Hayhurst,[3] goiter is associated with districts of glacial formation in contradistinction to districts of nonglacial formation. Districts of glacial formation contain less iodine in the soil and in the water supply than do districts of nonglacial formation, because the soluble sodium salts of iodine have been removed by the melting ice. The goitrous area in the United States is that part of the country which was covered by the three great ice sheets, the lower border of which extended from the eastern part of New York State, south below Cincinnati and nearly to the Pacific coast.[4]

How unwarranted it may be to assume infrequency of simple goiter or goiter of a mild type along the sea coast merely because of proximity to the ocean has recently been indicated in The Journal[5] in relation to conditions in New Zealand. Mere geographic location is not the only factor that protects or involves. The distribution of iodine in the soils and foods is highly significant. The actual facts of goiter incidence therefore help to prevent a false sense of security in a supposedly "safe" locality. They may also avert unnecessary concern in other regions. Thus, observations on about 12,000 school children in New York show a relatively small number of deviations from the thyroid normal, so that the metropolis can truly be termed a "nongoitrous" center. According to Frances Cohen,[1] who made the survey, the incidence of simple goiter in school children and in the older group of women, and the investigation into the conditions of iodine intake which determine endemic centers of goiter, do not justify a conclusion that New York City is an endemic center of goiter. The mild sporadic cases of simple goiter that occur among school children seem to be dependent on a relative insufficiency of iodine, due mainly to a physiologic cause; namely, puberty. Thyroid enlargements occur in New York about three times more frequently in girls than in boys. Simple goiter among children in New York reaches its peak at puberty, between the ages of 13 and 15, in both girls and boys. The percentage of incidence of normal glands seems to vary inversely with the degree of activity of the menstrual cycle. The mild cases of simple adolescent goiter observed among children in New York seem to show, in the case of girls, a distinct tendency to spontaneous regression after puberty; in that of boys, a complete regression.

Such observations, it is argued, do not justify a recommendation for the adoption of general municipal or school administered prophylaxis as a public health measure in New York. Individual prophylaxis, the early recognition and cure by individual physicians, and public health education in goiter prevention and cure would seem adequate. There is presumable wisdom in Frances Cohen's advice that, because of the comparatively small incidence of simple adolescent goiter in New York, its mild type and its tendency to regress spontaneously after puberty, great care should be taken not to alarm the public by unduly or unwisely stressing the conditions.

THE FORMATION OF BILE PIGMENT

The old story of the bile pigments within the body has been entirely rewritten. The new presentation has not been the result of a single stroke of experimental good fortune or scientific intuition, but has been developed chapter by chapter through substantial investigation, mostly in American laboratories. Experimental technic has played a significant part in the success of the newer discoveries. They were not the incidental by-product of the clinic.

The liver has lost its extreme dominance in relation to the genesis of the bile pigments. Reviewing the subject little more than a year ago, Rich[1] of Johns Hopkins University felt justified in stating that we are unable to speak with certainty concerning the exact rôle of the liver in normal bile pigment formation except so far as we are sure that the epithelial liver cell is not necessary for the formation of the pigment. The latter was thus made independent of the activity of the hepatic tissue. Rich remarked that previous to 1903, whenever it was suggested that perhaps the liver cells merely excrete the bile pigment which is made somewhere outside them and carried to them by the circulation, it seemed rather easy to refute the suggestion by the statement that there is no bile pigment in the blood stream normally—not even in the portal vein. The important demonstration by Gilbert, Herscher and Posternak[2] that normal human serum does contain bile pigment removed this well worn prop from the theory that the pigment is made within the liver cells. In 1913, van den Bergh and Snapper[3] applied Ehrlich's diazoreaction to the quantitative study of bilirubin in the body fluids. This work, Rich adds, really marked an epoch in the study of bile pigment under physiologic and pathologic conditions, for it placed in the hands of every one interested in the matter a simple and extremely sensitive test for bilirubin in albuminous fluids. With the van den Bergh test, the observation of Gilbert and his co-workers has been confirmed repeatedly, and it is now a perfectly familiar fact that bilirubin is normally present in human plasma in amounts that vary within fairly definite limits.

Mann and his collaborators at the Mayo Foundation have greatly promoted these convictions by their beautiful demonstrations that bilirubin is formed in the body even after the surgical removal of all the intra-abdominal organs, thus conclusively demonstrating that there is an extra-abdominal source of bilirubin and that neither the liver nor any other of the intra-abdominal organs is necessary for its formation. In rapid succession they[4] ascertained some of the localities involved. A comparison of the bilirubin content, as measured by the spectrophotometer, was made of the arterial and venous blood of most of the large organs of the body and other isolated vascular areas. In most of the vascular areas, the bilirubin content of specimens of blood from the two systems was the same, but the bilirubin content of the venous blood was greater than that of the arterial blood of spleen and bone marrow, which proves that bilirubin is formed in these organs at least. The latest reports from the laboratories at Rochester, Minn., give added support to the belief that the blood pigment hemoglobin can act as a precursor of bilirubin in the sites of formation just referred to.[5] The appearance of hematin, which the Mayo Foundation investigators discovered in connection with the active formation of bilirubin, would indicate that the process of disintegration of hemoglobin into hematin and globin occurs more rapidly than the formation of bilirubin from hematin. Thus, the presence of hematin in the blood in disease might easily be interpreted as evidence of increased destruction of hemoglobin. This interpretation, we are reminded, would apparently be of considerable importance in the study of hemolytic icterus and also of value in differentiating the various types of anemia. A summary of our knowledge thus should indicate that: the liver is not the principal seat of formation of the bile pigments; bilirubin is formed in the spleen and marrow; bilirubin is formed from hemoglobin; hematin appears as an intermediate product in the formation of bilirubin from hemoglobin.

RESPIRATORY CHANGES IN AIRPLANE FLIGHTS

The modern world sometimes calls for the adjustment of persons to environmental conditions that represent extremes in contrast with usual circumstances of everyday life. Man is penetrating the tropical jungles and likewise being transported literally to the uttermost ends of the earth, not only in the arctic but also in the antarctic regions. He is obliged to encounter heat and cold in their severest manifestations; nor is this all. Rising above the level of the sea anywhere up to the height of seven miles, already attained, he is confronted with a gradually attenuated atmosphere and a consequent lowered partial pressure of oxygen. It has long been known that high altitude is provocative of disagreeable symptoms that may become aggravated into severe distress. The conquest of the higher air has necessitated the acquisition of complete understanding of the physiologic effects of altitude. There was a time not long since when these were catalogued under the designation of "alpine physiology" in recognition of the circumstance that the study of the subject had largely been confined to investigations in mountaineering, notably in the high Alps, where some of the classic researches were conducted for many years. Today, with the advent of the airplane and the dirigible, a science of aviation physiology is in process of development.

The fundamental thesis that has been stressed places emphasis on anoxemia, due to a fall in the oxygen tension in the lungs, as the chief provocative factor in the distress that may arise at great heights, whether on mountain tops or in airships of one sort or another. It is not always possible or convenient to establish laboratories in such locations; consequently, physiologists have attempted to imitate the expected atmospheric conditions of altitude by the use of chambers in which the atmospheric pressure can be reduced to any desired magnitude. Cold and wind can thus be eliminated in the consideration of the fall in oxygen tension Similar results have been attempted in closed chambers where rebreathing the contained air also brings about reduction in the oxygen supply. Both methods have been extensively applied in the examination of candidates for the aviation service.[1]

It has been clearly established that high altitudes or low barometric pressure when first encountered may interfere with the normal workings of the human machine. The consensus developed from such studies is that the physiologic effects noted at high altitudes are due to the lack of oxygen resulting from the lowered partial pressure of oxygen. Schneider and Clarke[2] of the School of Aviation Medicine at Mitchel Field have remarked that occasionally doubt is expressed as to whether the effects of a flight to a high altitude are the same as those produced when these altitude changes are simulated by means of the low pressure chamber or by the rebreathing method of producing anoxemia. Changes in the composition of the alveolar air of the lungs give information regarding the extent of ventilation of the lungs, the supply of oxygen, and chemical changes in the blood. Hence, they have determined the changes in the alveolar carbon dioxide during flights to an altitude of 15,000 feet. The technic of making satisfactory physiologic observations with delicate apparatus during a flight in an airplane is particularly difficult because of the cold and wind.

The ventilation of the lungs was increased in some instances at altitudes of 2,000 and 3,000 feet, but in one case not until 10,000 feet had been passed. The alveolar carbon dioxide tension remained below normal for some time after the flight. A comparison of the respiratory conditions of airplane flights with those of anoxemia produced in other ways shows that the changes are chiefly those of lack of oxygen. In airplane flights, the alveolar oxygen tension is slightly higher than under conditions of simulated altitude. The difference is attributed to the favoring action of wind on pulmonary ventilation. However, the sensations of the persons when at 15,000 feet were not alone those of anoxemia, although there were observed an increase in breathing, especially frequent deep sighs, and occasionally periodic breathing of the Cheyne-Stokes type. One subject developed a headache, another was nauseated and vomited several times, and still another noticed that slight exertion produced dizziness. All found the effects of the cold quite severe; the temperature in the cockpit frequently fell to between 10 and 15 F. The face, neck and hands were most affected; but the legs and feet were also often noticeably cold. These are incidents independent of the barometer; they can in large part be averted by suitable clothing and protective devices. Anoxemia, on the other hand, calls for an artificial supply of oxygen when a man leaves the regions in which it is furnished under adequate conditions.

Current Comment

MUSCLE HEMOGLOBIN

Hemoglobin, oxygen carrying and the blood are so commonly considered in an interrelated way that it is not easy to divorce this respiratory pigment from immediate connection with the circulation. It has been known for many years, however, that the muscles contain a red pigment that is not removed by merely washing out the residual blood from the contractile tissues. Recent investigations by Whipple[1] and his collaborators at the University of Rochester, N. Y., point to the probability that muscle hemoglobin and blood hemoglobin are almost indistinguishable, if indeed they are not chemically identical. Accordingly, it becomes important to ascertain the origin, function and possible interrelations of the muscle pigment. The muscular tissues represent a large fraction of the body mass; from a quantitative standpoint, therefore, the function of any component may be significant even if it is present in comparatively small proportions. Representing total circulating hemoglobin of the dog as 100 Gm., the Rochester group found the total muscle hemoglobin amounting to from 10 to 80 Gm. in widely different conditions. They regard it as obvious that muscle hemoglobin is of importance whether one studies the end-products of hemoglobin disintegration or the parent substances suitable for construction into mature hemoglobin. Muscle hemoglobin must be considered in any study of body pigment metabolism. The muscles appear to have a great range in their muscle hemoglobin content which appears to depend on exercise and to determine largely the latent muscular power. This is in harmony with the popular assumption that "flabby" muscles are as a rule pale. The heart is much more uniform in its muscle hemoglobin content, just as its work is more steady and uniform than the work of the skeletal muscles. Whipple has found that anemia demands cannot rob the striated muscle of its hemoglobin. The body ranks the necessity for muscle hemoglobin maintenance on a par with the need for blood hemoglobin production, and from the standpoint of survival of the individual Whipple regards that as a fortunate circumstance. It also shows the importance of muscle hemoglobin in body economy and general pigment metabolism. Muscular paralysis is followed by fairly rapid loss of muscle hemoglobin. Evidently exercise is more important than anemia in determining the content of muscle hemoglobin.

VITAMIN B AND "VITALITY"

A word for popular writers on health topics to conjure with is "pep," defined according to the special point of view of the enthusiast who uses it. Basal metabolism is in some respects an index of health. Deviations from the normal may indicate conditions that are disagreeable if not actually disastrous. Readjustment of a disordered basal metabolism is not always easy without drastic measures. A recent writer[1] has remarked that while no satisfactory measure of an animal's vitality can be said to have been discovered, it is becoming increasingly evident that the intensity of the basal metabolism varies directly with an animal's physiologic condition. For example, athletes are known to have a higher basal metabolism than untrained persons, and men a higher basal metabolism than women; debilitating diseases are known to lower the basal metabolism, while convalescence is accompanied by an increased metabolism. During the excessive enthusiasm a few years ago for the then newly discovered vitamins and the exalted hope of great physiologic accomplishment through their administration in a therapeutic or prophylactic way, these food factors—notably the vitamin B of yeast—were often expected to "pep up" the jaded person. Somehow it was assumed that the vitamin must "stimulate" one function or another. The actual investigations have, however, been disappointing in some ways. Secretion has not as yet been discovered to be stimulated or "pepped up" in any way, although efforts have been directed to a study of the possibility, notably by Cowgill[2] at Yale University. Deuel and Weiss[3] of Cornell University Medical College have demonstrated that deprivation of vitamin B does not of itself lower the basal metabolism, nor is the latter altered by large doses of vitamin-bearing products. These results were secured on dogs. Now Mitchell and Carman[1] of the University of Illinois have demonstrated that the ingestion of excessive amounts of vitamin B up to about ten times their estimated requirements does not appreciably modify the basal heat production of rats. Therefore, so far as the basal heat production is a measure of "vitality," it may be concluded that the ingestion of amounts of vitamin B in large excess over the minimum requirements for growth and continued well being does not benefit an animal.

ALABAMA

Supreme Court Upholds Birmingham Ordinance.—The Supreme Court of Alabama rendered a decision, June 10, upholding the city commission of Birmingham in abolishing, by ordinance, Nov. 17, 1925, the office of municipal surgeon. The case was appealed from the Jefferson Circuit Court in equity on the ground that it was an attempt to evade the civil service law. Justice Summerville, of the supreme court, said, it is reported, that although an office is properly subject to civil service regulations, so that an employee cannot be removed except for cause and in accordance with regulations, the municipal government may, nevertheless, abolish the office or position and thereby remove the incumbent, provided the ordinance or resolution is adopted in good faith, and provided the office is not created by the municipal charter or by general law.

CALIFORNIA

Chinese Herbalist Fined.—T. How Wing, a Chinese herbalist of Los Angeles, was arrested recently on a charge of violating the medical practice act; he pleaded guilty and was fined $100.

Physician Cited.—A citation has been issued by the state board of medical examiners calling Dr. Jacob L. Owen, Los Angeles, before the board at the July meeting to show cause why his license should not be revoked for an alleged violation of the Harrison Narcotic Law.

Award of Clinical Prize.—The California Medical Association recently awarded its clinical prize of $150 to Dr. Emil Bogen, Los Angeles, for his essay on "Arachnidism, a Study of Spider Poisoning." No prize for original research was awarded. The council decided to continue the prize committees and to offer similar prizes to be awarded at the 1927 meeting.

Present Status of Poliomyelitis.—The state board of health bulletin, June 5, tabulates the number of cases of poliomyelitis in California in the last five years. There was a total of 283 cases reported in 1921, the largest number until 1925, when the total was 802. In the first five months of 1926 there were fifty-eight cases reported, the largest number in the corresponding period in any of the preceding six years, except 1925, when the number was ninety-nine.

Society News.—The Los Angeles County Medical Association devoted the May 6 meeting to the subject of smallpox; Dr. George Parrish discussed "Management of the Recent Epidemic"; Dr. George M. Stevens, "Hospital Care of Smallpox," and Dr. Michael S. Creamer, "Lessons to Be Learned from the Recent Epidemic."——Dr. George Piness, Los Angeles, addressed the San Diego County Medical Society, June 8, on "Allergic Manifestations, Diagnosis and Treatment."

New Health Officers.—The state board of health notes in its weekly bulletin the following changes in health officers:

Dr Smith A. Quimby succeeds Dr. George G Hawkins as health officer of Madera County
Dr Robert J. Evans, Jr, succeeds Dr George McKenzie as city health officer of Concord
Dr. Gordon L. McLellan has been appointed city health officer of San Leandro
Dr Glenn T. Logsdon succeeds Dr Henry F. Crandall as city health officer of Oceanside
Dr Harrison M Hawkins succeeds Dr Marcus W Pascoe as city health officer of Taft
Dr Edgar R Brigham succeeds Dr C A Tillotson as health officer of Dinuba
Dr Frederick R Rhodes succeeds Dr Foster M Hull as health officer of Culver City
Dr George Rothganger succeeds Dr Emily Emery as city health officer of Emeryville
Dr Francis F Malone succeeds Dr Lawrence L Lindsey as city health officer of Calipatria
Dr Fred R DeLappe, Modesto, succeeds Dr Benjamin F. Surrhyne as health officer of Stanislaus County

FLORIDA

Smallpox Embargo Removed.—The health restrictions and shipping embargo placed against Florida ports by the Bahama Islands on account of the recent smallpox situation were removed early in May

Hospital News.—The citizens of Fort Pierce have voted a bond issue of $250,000 for a municipal hospital, the construction of which, it is expected, will be undertaken this fall.——Dr Grover C Hardie has been appointed medical director of the Fort Pierce Hospital

Society News.—At the sixth annual meeting of the Florida Railway Surgeon's Association, Gainesville, May 3, Dr Joseph N. Fogarty, St Augustine, was elected president; Dr. George C Tillman, Gainesville vice president, and Dr Edmund W. Warren, Palatka, secretary-treasurer, the next meeting place will be West Palm Beach——Dr. Roy O Cooley has been elected president of the Palm Beach County Medical Society, Dr Alice R Miller, vice president, and Dr Wilbur O Arnold, secretary-treasurer.

ILLINOIS

Chiropractor Sentenced.—A B Croessman, a chiropractor of Rockford, was recently fined $100 and sentenced to one day in jail for practicing without a license, it is reported.

Student Nurses Strike.—Twenty-five student nurses at the Galesburg Cottage Hospital, Galesburg, went on strike, June 17, it is reported, in protest to the dropping of three nurses from the training school who failed to pass the examinations The nurses were given time to return to their studies and work without penalty, only one returned, the other twenty-four student nurses were expelled by the hospital board Meanwhile, the patients in the hospital are being cared for by graduate nurses from nearby cities

Annual Beaumont Award.—The first Annual Beaumont Award will be made in 1927 by a faculty committee of the University of Illinois School of Medicine for the most important clinical or research work contributed during the year in the field designated The award is available to workers in any institution and is not confined to members of either faculty or student body of the University of Illinois Manuscripts do not have to be entered specifically for the award or submitted to the faculty committee The award is to be granted by the committee after considering all investigations published during any year in periodicals in the United States The object of the donor, Dr. Frank Smithies, was to encourage investigations of the alimentary tract function The award will be not less than $100

Chicago

Liquor Licenses Revoked.—Mr E C Yellowley, local prohibition administrator, recently announced the revocation of the alcohol permits of the following, it is reported·

Dr Charles A Lapin, 613 South Sacramento Boulevard
Dr Alexander B Raff, 817 Independence Boulevard
Drs Nathan N Fox, 1317 Independence Boulevard, and Nicholas I. Fox, 170 Taylor Street, Oak Park
Dr Henry C Welcker, 2742 North Clark Street
Dr Alexander Levin, 2719 Crystal Street
Dr Martin A Schupmann, 2000 North Halsted Street
Dr Adolph Kleinwachter, 2309 North Ridgeway Avenue

Dr. Pelton Appointed Superintendent of St. Luke's.—Dr. Charles H Pelton, superintendent of the Elyria Memorial Hospital, Elyria, Ohio, has been appointed superintendent of St Luke's Hospital, Chicago, and will take up his new duties about July 1 Dr Pelton has been superintendent of the Elyria Memorial Hospital for about four years, and previous to that appointment he was assistant to the late Dr. Arthur B Ancker, in whose honor the city and county hospital at St. Paul was named the Ancker Memorial Hospital.

Nurses' Training School for University of Chicago.—The Illinois Training School for Nurses, which, for about forty-five years, has served the Cook County Hospital, will be transferred to the University of Chicago. When the Cook County commissioners have completed other arrangements *for the nursing of patients in Cook County Hospital, the* property and resources of the Illinois training school, involving about $500,000, will be turned over to the university, making possible a school for nurses in connection with the university medical program on the South Side. Not less than $1,000,000 will be required to endow the undertaking, and this fund must come from benefactors who see the significance of the project. The board of directors of the Illinois Training School for Nurses comprise, among many others, Mrs Harry F. Williams, president; Mrs. Charles T. Mordock, corresponding secretary; Miss Augusta Fenger, Mrs. Bertram Sippy and Mrs. Charles H. Wacker.

Sale of Poisonous Shoe Dyes Prohibited.—The department of health of Chicago has issued an order prohibiting the sale or use in the city of leather dyes containing toxic solvents on and after March 1, 1927, and requiring that all shoe dyes *offered for sale or used from June 1, 1926, to March 1, 1927,* shall have a "caution label" as follows: "Shoes that have been dyed must be permitted to stand in the open (not wrapped up) for not less than seventy-two hours after dyeing, before being worn, in order to avoid poisonous effects to the wearer This dye must not be used on canvas, satin or other shoes manufactured from fabrics. Under no circumstances should shoes or edges of the soles of shoes be dyed while on the feet." A notice will be posted in every shoe shop, shoe-shining parlor, and any place where shoes are dyed, and any person failing to comply with the foregoing order will be prosecuted under section 2916 of the municipal code, or the dye materials destroyed, or both. This section is taken as a public health measure, and the health commissioner requests the cooperation of all concerned.

MAINE

State Medical Election.—At the annual meeting of the Maine Medical Association, Poland Springs, June 10-12, Dr Lester P Gerrish, Lisbon Falls, was elected president; Dr Nathaniel M. Marshall, Portland, president-elect; Drs. Thomas S Dickison, Houlton, and Ward J. Renwick, Auburn, vice presidents, and Dr. Bertram L. Bryant, 265 Hammond Street, Bangor, secretary-treasurer.

MASSACHUSETTS

State Medical Election.—Dr. James S. Stone, Boston, was elected president of the Massachusetts Medical Society at the annual meeting, June 8; Dr. John M. Birnie, Springfield, vice president, Dr Walter L Burrage, Brookline, secretary; Dr. Arthur K Stone, Framingham Center, treasurer, and Dr. William H Rose, Worcester, orator. The total registration at this meeting was 706, and in addition there were 185 women present. The next meeting will be in Boston, June 9-19, 1927

Gift to Hospitals.—Eight hospitals and the Boston Museum of Fine Arts will eventually share equally in the residue of the estate of the late Wilmot R. Evans of Newbury, estimated for the purposes of bond at more than $3,500,000. The hospitals are Massachusetts General Hospital; Boston Lying-In Hospital; Boston Home for Incurables; Anna Jacques Hospital, Newburyport; Everett Cottage Hospital; Everett Home for Aged Persons; Cambridge Hospital, Cambridge, and Children's Hospital of Boston.

State Tuberculosis Program.—To assist in the program of the state department of health to prevent the development of pulmonary tuberculosis in adult life, the Boston Department of Health began in 1925 the physical examination of school children below the grade of high school. Thus far there have been selected for the purposes of the program more than 78,000 children, the selection being based on an apparent deficiency in weight and height. Of this number who have been made subject to special attention, 8,874 have been selected for special physical examination, and of these 6,561 had undergone this examination at the time of this report. On the evidence presented by roentgenograms, 541 children were said to have hilum tuberculosis, either active or latent, or to be suspicious. The entire procedure, thus far in Boston has disclosed only four cases of active pulmonary tuberculosis.

MINNESOTA

Committee to Confer with University Representatives.—In accordance with a resolution adopted by the house of delegates of the Minnesota State Medical Association, a committee has been appointed to confer with the president of the University of Minnesota and other representatives to consider what the policy of the university shall be concerning problems affecting the medical school. The resolution passed was, in part, as follows:

> *Resolved,* That the Minnesota State Medical Association disapproves of the general policy of admitting pay patients to the University Hospital; be it further
>
> *Resolved,* That a committee of seven, including the president of the association, Dr. Herman M. Johnson, who shall be an active member of this committee, be appointed by the president of the association, and after having fully informed themselves concerning the problems affecting the medical school, arrange a conference between this committee of the association, the president of the University of Minnesota and representatives of the board of regents of the university to consider what the future policy of the university shall be concerning these problems and other problems which may present themselves concerning the medical school and the medical profession; be it further
>
> *Resolved,* That the Minnesota State Medical Association reasserts its stand previously taken against the socialization of medicine and state medicine; be it further
>
> *Resolved,* That the members of the Minnesota State Medical Association do hereby express their willingness to cooperate with the board of regents of the State University of Minnesota and others in authority to the end that an abundance of suitable clinical material, secured entirely from the ranks of the worthy poor, may be available for medical instruction, and pledge their support in securing public and private funds for this purpose.

MONTANA

Personal.—Dr. Thomas H. Handbidge, Circle, has tendered his resignation as health officer of McCone County.——Dr. Hiram B. Cloud, Medicine Lake, has been appointed health officer of Sheridan County.——Lieut. Col. James T. Arwine, Helena, medical reserve, was ordered to active duty for training at American Lake, Wash., effective, June 13; similar orders were issued by the War Department for Lieut. Earl C. Hall, Ashton.

NEW JERSEY

State Medical Election.—At the annual meeting of the Medical Society of New Jersey, June 17-19, at Atlantic City, Dr. James S. Green, Elizabeth, was elected president; Drs. Walt P. Conaway, Atlantic City, Ephraim R. Mulford, Burlington, and Andrew F. McBride, Paterson, vice presidents; Dr. John B. Morrison, Newark, recording secretary; Dr. William J. Carrington, Atlantic City, corresponding secretary, and Dr. Elias J. Marsh, Paterson, treasurer. The society adopted resolutions authorizing the establishment of permanent headquarters, and a committee was appointed to perfect the plans; Dr. James Hunter, Jr., Westville, is chairman of the committee.

Society News.—Dr. Hannah M. Stone, clinical director, American Birth Control League, addressed the Asbury Park Medical Society, recently, on "The Technic of Contraception." ——Dr. Joseph F. Montague, New York, addressed the Passaic County Medical Society, Paterson, recently, on "Popular Fallacies Concerning Hemorrhoids," illustrated by motion pictures. The society gave a dinner, June 8, in honor of its oldest member, Dr. James M. Stewart, Paterson, at the North Jersey Country Club.——Dr. Henry H. Brinkerhoff retired in May after thirty-two years of service as treasurer of the Hudson County Medical Society, Jersey City; Dr. Brinkerhoff received a standing vote of thanks from the society, was made an active member without payment of dues, and will be the guest of honor at the next annual dinner.——Dr. William S. Bainbridge, New York, recently addressed the quarterly meeting of the Middlesex County Medical Society on "The Present Status of the Cancer Problem."

NEW MEXICO

Rocky Mountain Diarrhea.—The U. S. Public Health Service has assigned, according to the Bureau of Public Health of New Mexico, Surg. J. G. Wilson to make a thorough study of the annual outbreak in the Rocky Mountain region of an acute diarrheal condition that numbers its victims by hundreds. Limitation of funds, it is said, will prevent Dr. Wilson from visiting localities that have a small number of cases. Health officers are requested to keep in touch with physicians and their counties, and when an outbreak is developing to wire the state department of health, which will notify Dr. Wilson. Detailed records should be kept of such cases to assist in the investigation.

NEW YORK

Personal.—Charles W. Dodge, after thirty-one years of service, has retired, at his own request, as bacteriologist in the bureau of health of Rochester.——A testimonial dinner in honor of Dr. Henry L. K. Shaw, chairman, committee on legislation, was given at the University Club, June 15, by the Council of the Medical Society of the State of New York, for his leadership in behalf of the Webb-Loomis bill, amending the medical practice act.

Vaccination Stops Quarantine.—Twelve cases of smallpox reported at Cold Spring caused a quarantine to be established at Camp Smith, where about 1,200 national guard troops are in camp for training, including the One Hundred and Second Medical Regiment, comprising units from New York, Albany, Rochester and Ticonderoga, and the One Hundred and Second Engineers, from New York. The entire personnel of the camp was vaccinated, June 19, following which the quarantine restrictions were removed.

History of Medical Society.—The Seneca County Medical Society is collecting biographic records of all physicians who ever practiced medicine in the county and also records of the county society; these will be compiled in a history of the society by Drs. Lester W. Bellows, Waterloo, and Albert J. Frantz, Seneca Falls. Some biographies already obtained go back as far as 1792, and all of the society records are intact as far back as 1865. The Seneca County Medical Society is 116 years old. Ethical physicians who have not given the data desired are requested to write promptly to Dr. Bellows, as the history is expected to be placed before the society for approval this fall.

New York City

Personal.—Dr. James F. Cooper, of the American Birth Control League, is reported as having made another tour in April and May, addressing state and county medical societies and other organizations in Colorado, New Mexico, Arizona and Florida.——Dr. Smith E. Jelliffe has been made a corresponding member of the Vienna Society of Psychiatry and Neurology.——Dr. Howard Fox has been appointed chairman of the newly organized section on dermatology and syphilology of the Medical Society of the State of New York.——Dr. Morris Levine has been promoted to associate professor of otology, New York Post-Graduate Medical School and Hospital.——The faculty and management of Long Island College Hospital were hosts, June 5, at the Hamilton Club, to Drs. William Browning and Henry H. Morton, professors at that school for forty-four and thirty-one years, respectively. ——Dr. Alexis Carrel and Pierre Lecomte du Noüy, D.Sc., of the Rockefeller Institute for Medical Research, sailed for France, June 5.——Drs. and Mesdames Louis L. Seaman, Fred H. Albee and Richard Kovacs entertained members of the Travel Study Club of American Physicians at dinner at the Army and Navy Club, June 11, previous to their sailing the next day on a visit to medical centers in Europe.——Dr. William H. Park received the honorary degree of doctor of science from New York University at the commencement, June 9.——T. B. Kidner has resigned as institutional secretary of the National Tuberculosis Association and has been succeeded by Mr. Jamieson Marshall.——Henry J. Fisher, president of the United Hospital Fund of New York, recently went to England to study the administration of King Edward's Hospital Fund for London, which, it is said, promotes coordination among 118 London hospitals, and makes an annual campaign for funds toward their support.——Dr. Otto Glogau is president of an organization of Americans of German and Austrian descent, which collects funds for Germanic art reproductions in America; a delegation recently went to Harvard University to unveil, at the Germanic Museum of the university, three replicas of masterpieces of medieval sculpture, and gave to the museum a check for the purchase of an additional gift.——Dr. Lawson G. Lowrey, now engaged in child guidance work in Cleveland, has been appointed director of the Institute for Child Guidance, which has just been established in this city to carry out a comprehensive program of community mental hygiene.——Dr. Francis C. Wood sailed for Liverpool, June 19, to complete his studies with Prof. W. Blair Bell of the results of treatment of cancer with colloidal lead.

OREGON

Naturopath Indicted.—J. C. Ritter, a naturopath of Portland, was indicted, it is reported, by the March grand jury on a charge of manslaughter, based on a death alleged to have been due to an illegal operation; Ritter is out under $5,000 bail.

Hospital News.—The Lutheran Church of the Columbia Conference has taken over the hospital property in Astoria at Sixteenth and Franklin streets, where a fraternal hospital association started to build.——The Salem Hospital will build a new thirty-bed wing, costing $60,000.

Personal.—Arthur R. Moore, Ph.D., professor of physiology and biochemistry, Rutgers University, Brunswick, N. J., has accepted the position of professor of zoology at the University of Oregon.——Dr. David E. Wiley, Hillsboro, resigned as county health officer, June 1.——Lieut. Col. William C. Smith, medical reserve, was ordered to active duty for training at American Lake, Wash., effective, June 13.

SOUTH CAROLINA

Graduation at Medical School.—At the recent graduating exercises of the Medical College of South Carolina, Charleston, the following changes in the faculty were announced: Dr. William P. Rhett has been appointed assistant in surgery; Drs. George H. Zerbst and Roderick Macdonald, assistants in ophthalmology and otolaryngology; Dr. Sedgwick Simons, instructor in clinical pathology to succeed Dr. Hugh E. Wyman, resigned, and Dr. Thomas H. Martin, appointed lecturer in surgery. The Manning Simons scholarships, established in memory of the late Dr. Manning Simons, who for years was professor of surgery, were awarded to James O'Hear, Jr., of the sophomore class, and Gerald E. McDaniel of the junior class. The degree of doctor of public health was conferred on Dr. James A. Hayne of Columbia. There were thirty-eight graduates in medicine.

WASHINGTON

Hospital News.—Dr. Lawrence H. Meadows has moved to Port Gamble to assume charge of the McCormick Lumber Company hospitals.

Annual Postgraduate Lectures.—The tenth postgraduate course of medical lectures given under the auspices of the University of Washington will be delivered, July 19-23, in Anderson Hall; Dr. George Dock, Pasadena, will give the medical lectures; Dr. William F. Braasch, Mayo Clinic, Rochester, Minn., the urologic lectures, and Dr. F. W. Rankin, of the Mayo Clinic, the surgical lectures; each speaker will lecture daily for five days. In addition, a public health lecture under the auspices of the university will be delivered Wednesday; there will be a banquet Monday evening, and alumni reunions Tuesday evening.

State Medical Meeting.—The annual meeting of the Washington State Medical Association will be at Spokane, June 28-30; the county health officers of the state will also hold their annual meeting at this time. Dr. Hans Lisser, associate professor of medicine, University of California Medical School, will give a lantern slide demonstration on "Pituitary Syndromes," June 29; Dr. Maurice F. Dwyer, Seattle, will discuss "Gastric Lesions," and Dr. John C. Lyman, Walla Walla, "Improvement of Our Poor Surgical Results." The public health league will hold its luncheon and general meeting at noon, Tuesday; there will be a dinner dance in the evening at the Davenport Hotel. Dr. Howard Lilienthal, professor of clinical surgery, Cornell University Medical College, New York, will speak on "Empyema," and Dr. Charles D. Hunter, Tacoma, on "Etiology and Treatment of Nonunion of Fractures," and Dr. Clarence A. Smith, Seattle, on "Application of Physiotherapy." There will be a smoker, Wednesday evening, in addition to other entertainment which will insure an enjoyable visit to Spokane.

LATIN AMERICA

New Chief of Public Health Service.—Dr. Francisco María Fernández, Havana, has just been appointed chief of the public health service in Cuba; he is president of the local medical society and of the Círculo Médico de Cuba, and is director of the *Crónica Médico-Quirúrgica* of Havana. Cuba is one of the few countries in which the chief of the public health service is a member of the cabinet.

First Pan-American Congress on Tuberculosis.—The city of Córdoba, Argentina, is preparing for an important conference on tuberculosis in its medical, social, economic and biologic aspects. It will convene, Oct. 10, 1927. Dr. Juan F. Cafferata, Córdoba, is president of the committee of organization, which includes the national and regional authorities. He urges the formation of subcommittees in cities throughout the Americas. The altitude and climatic conditions of Córdoba have made it a center for tuberculosis sanatoriums.

GENERAL

Discharge of Oil in Navigable Waters.—The American and British delegates to the Conference on Oil Pollution, held in Washington, D. C., to obtain an agreement for total prohibition of the discharge of oil from vessels on the high seas, reached a tentative agreement, June 12, on a system of zoning, under which vessels will be forbidden to discharge oil in navigable waters within a fixed distance from the shore. This resolution was reported to the conference after several sessions, during which there were discussions of various methods proposed for checking pollution of navigable waters by oil-burning and oil-carrying vessels. As tentatively agreed, the zoning resolution provides that the distance off shore shall not be less than 50 miles nor more than 150 miles, and that no zone may be established by a nation without the consent of neighbor nations. Members of the conference feel that one of the most important problems of the conference will be disposed of when the zoning plan is agreed on. The next problem is that of working out plans for enforcement.

Bequests and Donations.—The following bequests and donations have been announced recently:

The Albany Medical College, Albany, N. Y., $25,000; the Albany Associated Charities, $5,000, and the Albany Public Health Nursing Association, $5,000, by the will of Emily Niles Huyck.

The Home for Aged of the Little Sisters of the Poor, New York, $500, *and the New York Foundling Asylum, $500, by the will of Jane Nulty.*

The Eagleville Sanatorium for Consumptives, Eagleville, Pa., $25,000, and the Federation of Jewish Charities, Philadelphia, $5,000, by the will of Caroline Seidenbach.

The Illinois Children's Home and Aid Society, Duquoin, Ill., $50,000, by the will of the late Dr. Dwight J. Harris, Chicago.

The College of Physicians of Philadelphia, $5,000, by the will of the late Dr. S. Lewis Ziegler. Dr. Ziegler also bequeathed his library to the College of Physicians with the stipulation that it shall go to his son should he decide to become an ophthalmologist.

The New York Skin and Cancer Hospital; the St. Christopher Hospital for Babies; the Brooklyn and Jewish hospitals and the Graham Home for Old Ladies, each $5,000, by the will of William D. Hoxie.

The New York Skin and Cancer Hospital, $1,566, by the will of Edward Gordon.

The New York Post-Graduate Hospital; the Babies Hospital; People's Hospital and St. Christopher's Home for Children, Dobbs Ferry, N. Y., all of New York, each $101,000, by the will of Mrs. Anna Dodge McCullough.

Mount Sinai Hospital, $1,000; the Hebrew Orphan Asylum; the Home for Aged and Infirm and the Montefiore Home, all of New York, each $500, by the will of Caroline Adler.

White Plains Hospital, White Plains, N. Y., $10,000, by the will of Cornelius P. Young.

The Convalescent Home, Andalusia, Pa.; Eagleville Sanatorium, Eagleville, Pa., and the Jewish Hospital, Philadelphia, each $10,000, by the will of Fanny Rice.

The Mount Sinai Hospital, Philadelphia; the Uptown Hebrew Day Nursery and Downtown Day Nursery, each $500, by the will of the late Abram Waxman.

The Evangelical Deaconess Hospital, Brooklyn, N. Y., $5,000, by the will of Anna Heintz.

Brown University, Providence, R. I., and the United Hebrew Charities, New York, each $10,000, by the will of the late Oscar S. Straus, New York.

Mr. and Mrs. Booth Tarkington have donated $5,000 in memory of their daughter, and Mr. Carl Fisher $10,000 to the James Whitcomb Riley Hospital for Children, Indianapolis.

The Stamford Hospital, Stamford, Conn., has been given between $150,000 and $200,000, anonymously, to build a nurses' home.

The Hebrew Orphan Asylum, New York, $2,500; the Mineola Home for Cardiac Children, and the Permanent Blind Relief for Soldiers, each $1,000, by the will of Isaac Brill, New York.

The Manhattan Eye, Ear, Nose and Throat Hospital, New York, and the Hartford Hospital, Hartford, Conn., each $25,000, by the will of Mrs. Alice D. Jackson, New York.

The Home for the Aged, Brooklyn, $1,000, by the will of Mary F. B. Spalding.

The Niles Hospital Association, Niles, Mich., $5,000, by the will of Mrs. Sally Lipp.

The Federation of Jewish Charities, $500, by the will of the late Morris Strousse.

The Lutheran Hospital Association, New York, Lennox Hill Hospital, the Bethlehem Orphan and Half Orphan Asylum, each $1,000, by the will of Anna A. Kimme.

Mount Sinai Hospital, Lennox Hill Hospital and the Hebrew Orphan Asylum, all of New York, each $500, by the will of Jacob Manheimer.

The Good Samaritan Hospital, Lexington, Ky., recently received a gift of $55,000, through H. L. Ott, Crestwood, a member of the board of directors.

FOREIGN

Spain Founds a Council on Pharmacy and Chemistry.—Our Spanish exchanges bring the text of the royal decree organizing the Instituto Técnico de Comprobación for examining vaccines, serums, biologic preparations, proprietary medicines and disinfectants and foods for infants, to determine the truth or falsity of the claims of the manufacturers. The director is to be appointed by the government, but the other positions are to be filled by competitive examination. The institute is to be equipped from the funds obtained by the registering fee already imposed, and a stamp tax on proprietaries. The chief of the public health service, the dean of the faculty of pharmacy and the director of the provincial laboratory at Madrid have been appointed the committee of organization.

Deaths

John Howland ⊕ professor of pediatrics in Johns Hopkins University Medical Department, and pediatrician-in-chief of Johns Hopkins Hospital since 1912, died in London, June 20, following a surgical operation. He was born in New York, Feb. 30, 1873, the son of Judge Henry E. Howland and Louise Miller Howland. After receiving his early education in the public schools of New York, he attended the Phillips Exeter Academy. He received the degree of Bachelor of Arts from Yale University in 1894, and the degree of M.D. from the Medical College of New York University in 1897. Dr. Howland then served as house officer in the Presbyterian Hospital of New York from 1897 to 1899, and in the New York Foundling Hospital from 1899 to 1900. He studied abroad in Berlin and Vienna, and on his return to this country became pathologist and attending pediatrician to the Foundling Hospital. At various times Dr. Howland served on the staffs of the Willard Parker Hospital, the Riverside Hospital and St. Vincent's Hospital in New York City, and as instructor and associate in pediatrics in the Columbia University College of Physicians and Surgeons. In 1911, he was selected for the chair of pediatrics in the Washington University School of Medicine of St. Louis. Before undertaking this work, he spent a year in the children's clinics in Germany. In 1912, Dr. Howland received the offer of the position in the Johns Hopkins faculty, which he held at the time of his death.

Dr. Howland was associated with Dr. L. Emmett Holt of New York for twelve years, assisting him in the publication of the well known textbook, and, following Holt's death, acting as its editor. He had also been one of the editors of the *American Journal of Diseases of Children* since its foundation. In 1909, while acting as instructor in diseases of children in the College of Physicians and Surgeons of Columbia University, Dr. Howland was made a member of the Council on Pharmacy and Chemistry of the American Medical Association. Throughout his service on the Council, Dr. Howland was active, progressive and always without fear of consequences when plain speaking was in the interest of the advance of medical science. As a member of the Council's Committee on Therapeutics, and in accordance with the work to which he devoted his life, he was chiefly concerned in advising the Council in regard to the acceptance of medicines and medical foods used in the treatment of children. In addition, Dr. Howland took an active interest in establishing the value of biologic products. He was one of the Council's committee which prepared the series of articles, "Bacterial Vaccine Therapy," which appeared in The Journal in 1913, and which first definitely criticized the haphazard use of biologic products, particularly the "mixed" vaccines, which were gaining much vogue at that time and were threatening the scientific status of biologic therapy.

John Howland, M.D., 1873-1926

Dr. Howland has been recognized as a pioneer in American work on the fundamental requirements of infant nutrition. His research included studies on the metabolism of children, and important investigations on acidosis and on the calcium content of the blood in rickets and in tetany. He was recognized everywhere as a progressive and unselfish leader in the practice of pediatrics.

Carlos F. MacDonald ⊕ New York; Bellevue Hospital Medical College, New York, 1869; professor of mental diseases at his alma mater, 1888-1897, professor of mental diseases and medical jurisprudence, University and Bellevue Hospital Medical College, 1897-1906, and since 1906 emeritus professor; lecturer on insanity, Albany Medical College, 1892-1894; medical superintendent, Kings County Lunatic Asylum, 1873-1875; manager and consulting physician, New York State Inebriate Asylum, 1877-1879; medical superintendent of the Binghamton Asylum for Insane, 1879-1880, and of the State Asylum for the Insane since 1881; on the staffs of the Manhattan State Hospital and the Hackensack City (N. J.) Hospital; president of the New York State Commission in Lunacy, 1889-1896; member of the New York Psychiatrical Society and the American Psychiatric Association (president, 1913-1914); Civil War veteran; aged 80; died, May 29, at his home in Central Valley.

Russell Daniel Carman ⊕ for many years a leading roentgenologist, died of cancer of the stomach at Rochester, Minn., June 18, after a long illness. He was born in Iroquois, Ont., March 17, 1875. The degree of M.D. was conferred on him by the Marion-Sims College of Medicine, St. Louis, in 1901. After graduate study at the Johns Hopkins Medical School and Harvard, he took up the practice of medicine in St. Louis, specializing in roentgenology He was assistant in surgery on the faculty of his alma mater from 1902 to 1907, assistant in roentgenology from 1907 to 1909, and assistant professor of roentgenology from 1909 to 1910. He became lecturer in roentgenology in the Washington University in 1910, holding this position until 1913, at which time he went to the Mayo Clinic as head of its section on roentgenology, holding that position until his death. He was also professor of roentgenology in the Graduate School of the University of Minnesota.

The scientific contributions of Dr. Carman were recognized by his election to the presidency of the American College of Roentgenology and of the Radiological Society of North America. He was also a member of the International Congress on Radiology and of similar special organizations in several foreign countries. In addition to a book entitled "The Roentgen Diagnosis of Diseases of the Alimentary Canal," Dr. Carman contributed numerous observations to the literature on this subject, especially dealing with diagnosis of lesions of the gastro-intestinal tract. As a pioneer in the establishment of this specialty, he was generally recognized as a conservative and sincere leader.

Herbert T. Thornburgh, Cincinnati; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, Cleveland, 1898, member of the American Psychiatric Association; on the staff of the Longview Hospital, Cincinnati, and formerly on the staff of the Eastern State Hospital, Lexington, Ky.; aged 54; died, May 23, of injuries received in a fall while attempting to adjust an awning.

Charles Bates Dunlap, New York; Medical School of Harvard University, Boston, 1894; member of the New York Neurological Society, and the American Psychiatric Society; professor and formerly lecturer of neuropathology at the University and Bellevue Hospital Medical College; chief associate in neuropathology, New York State Psychiatric Institute; aged 62; died, June 6, at his home in Scarsdale.

Arthur J. Hill ⊕ Canton, Ohio; Western Reserve University School of Medicine, Cleveland, 1893; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staff of the Mercy Hospital; aged 54; died, May 12, of pernicious anemia.

Paul Bromley Godsman, Burlington, Colo.; Medical College of Ohio, Cincinnati, 1884; also a lawyer; formerly county judge, and member of the state legislature; aged 66; died, May 2, at Cheyenne Wells, of skull fracture received in a fall.

Oliver Groves ⊕ Rochester, N. Y.; Victoria University Medical Department, Toronto, 1887; formerly on the staff of the Royal Alexandria Hospital, Fergus, Ont ; aged 64, died, April 30, at Port Hope, Ont, of heart disease

Alvin Beckman, Bartlett, Texas, Medical Department of the Tulane University of Louisiana New Orleans, 1895; member of the State Medical Association of Texas, aged 55, was killed, March 28, when struck by a train

John Nelson Slown, Spencer, Ind (licensed, Indiana, 1897); member of the Indiana State Medical Association, aged 72, was killed, June 1, when the automobile in which he was driving was struck by a train

Banks Albert Shepherd, Lexington, Miss , Vanderbilt University Medical Department, Nashville, 1877, member of the Mississippi State Medical Association, aged 71, died, March 24, of lobar pneumonia

Robert Sanford Mitchell ⊕ Appleton, Wis , Northwestern University Medical School Chicago, 1904, member of the Radiological Society of North America, aged 48, died, May 17, of angina pectoris

William P. Kanar, Solvay, N Y , College of Physicians and Surgeons Baltimore, 1893 member of the Medical Society of the State of New York, aged 60 died, May 10, following a long illness

Percy Cobun Showalter, Clarksburg W Va Baltimore Medical College, 1910 member of the West Virginia State Medical Association aged 38 died May 2, of chronic nephritis

John W Haden, Plevna, Mo Missouri Medical College, St Louis, 1895, member of the Missouri State Medical Association, aged 55, died, May 10 of pneumonia and heart disease

John Benjamin Thomas, Wellington Ohio University of Wooster Medical Department Cleveland 1880 aged 69, died recently, of injuries received when struck by an automobile

Thomas S Greer ⊕ Edgerton Kan University Medical College of Kansas City, 1897 aged 64 died April 2 at the Christian Hospital, Kansas City Mo of duodenal ulcer

Frederick De Haven, Louisville Ky , Southwestern Homeopathic Medical College and Hospital Louisville, 1900, aged 61, died, May 2, of cerebral hemorrhage

David F Eakin, Spokane Wash , Cincinnati College of Medicine and Surgery, 1858 aged 85 died April 16 at La Grande, Ore , of cerebral hemorrhage

J T Slover, Sulphur, Okla Dallas Medical College, 1904 member of the Oklahoma State Medical Association, died, March 1, of carcinoma of the liver

William H Groves, Dixie, Ont Canada Victoria University Medical Department, Toronto 1889 aged 61, died, April 27, of cerebral hemorrhage

Charles T. Burnett, Newport Tenn , University of Louisville School of Medicine, 1892, aged 71, died, March 23, at Cartersville, Ga , of pneumonia

John Henry Sullivan, Mount Clemens, Mich Baltimore Medical College, 1898, aged 61, died, February 28, of arthritis and carcinoma of the stomach

Ephriam Ellsworth Gray, Bicknell, Ind Marion-Sims College of Medicine, St Louis, 1892, aged 65, died, February 19, of carcinoma of the liver

Frederick Rorbach, Johnsonburg, N J , Bellevue Hospital Medical College, New York, 1867, aged 80, died, April 26, of senility

Edward B Fetherston, Chicago, College of Physicians and Surgeons, Chicago, 1893, aged 64, died recently, of heart disease

John M Cullen, Chicago College of Physicians and Surgeons, Chicago, 1897, died, May 27, of chronic nephritis

J. W. Davis, Rineyville, Ky , Louisville Medical College, 1889, aged 87, died, April 2, of pneumonia

Marriages

Franklin August Weigand to Miss Marie Louise Haussmann, both of Philadelphia, May 26

Harold C Harpfer to Miss Esther Florence Evans, both of Wheeling, W Va, June 10

Moses Paulson, Baltimore, to Miss Helen Golden of Elkins, W Va, June 10

Lawson Wilkins to Miss Lucille Mahool, both of Baltimore, June 9

Fatal Hot Bath

An inquest was held at the Marylebone coroner's court on a woman, aged 46, who was found dead in a bath She was in the habit of taking very hot baths, and several years ago she fainted in one but recovered just in time to get out Dr R M Bronte, government pathologist, who made a necropsy, stated that there was marked anemia of the brain The condition of the lungs was not such as one would have expected in a case of drowning, and showed that on going under the water she was not breathing The heart was small only 7¼ ounces (200 Gm) instead of the normal 10¼ ounces (285 Gm) but was quite healthy. He attributed death to coma due to cerebral anemia The anemic condition of the brain might have been due either to the taking of a heavy meal before the bath or to the heat of the water The coroner asked It is a dangerous thing to boil yourself like that is it not?" Dr Bronte replied "Yes, particularly after meals The hot bath had the effect of drawing the blood away from the brain " Dr N S Gilchrist said that he attended the deceased regularly and saw her last on the day before death for the unsatisfactory state of her health since an operation for appendicitis last November She seemed to have no energy He arrived at the house Sunday morning about 9 o clock just before the police, and he found the bathroom door locked With the assistance of the police he helped to burst open the door In the bathroom they found her lying in the bath, with the water sufficiently high to cover her nose and mouth completely The electric light was still burning, and the water was not quite cold He formed the opinion that she had entered the bath about 10 or 11 o clock the night before and had been dead from eight to ten hours The coroner said that this was a case in which the cause of death was purely natural He could not exclude from his verdict, however, the fact that death was brought on by the hot bath The verdict, therefore, would be accidental death"

Barbituric Derivatives Declared Dangerous Drugs

A conference of representatives of the home office, the ministry of health the pharmacists and the British Medical Association has been held to discuss the measures necessary to obviate the dangers to the public from the unrestricted sale of barbital (veronal) and other derivatives of barbituric acid The home office experts produced evidence of many fatalities particularly from barbital, sometimes suicidal, but more frequently from an accidental overdose for sleeplessness London experience showed that in this respect barbital was the most dangerous drug in the pharmacopeia The representatives of the British Medical Association agreed that it was desirable to prohibit the retail sale of these drugs to unauthorized persons except on a medical prescription, but the pharmacists' representatives were opposed to this unless physicians were at the same time forbidden to supply the drugs, even to their own patients, and were required to order them by prescription, except in emergency or in districts where no pharmacies existed To this the British Medical Association representatives took exception as an interference, on a side issue, with the right of dispensing physicians, especially as there was no evidence of any untoward effects arising from the use of the drugs supplied in this way. The home secretary has taken steps to make regulations under the Dangerous Drugs Act to include among the drugs specified "diethylbarbituric acid and other alkyl, aryl or metallic derivatives of barbituric acid, whether described as veronal, proponal, medinal, dial, or by any other trade name, mark, or designation, and any preparation, admixture or other substance containing any of them." The effect will be to make it unlawful to supply by retail any of these drugs except (1) to a physician (2) for use in hospitals or similar institutions, (3) to persons authorized by the secretary of state, (4) in accordance with a prescription given by a physician. Prescriptions for the drugs must be dated and signed by the physician and bear his address, and they must specify the name and address of the patient and the total amount of the drug to be supplied. Where physicians dispense their own medicines and make an entry in their day book with particulars of the drug and the name and address of the patient and the date of supply, no further record is required. The drugs may not be supplied more than once on the same prescription; provided that, if the prescription so directs, the drugs may be supplied on more than one but not exceeding three occasions, as directed in the prescription, at intervals to be specified.

Injury from a Hair Dye

Another case in which injury from a hair dye was the subject of legal action has occurred. A woman used the preparation known as "Inecto" (of which the composition was not declared but of which the active ingredient appears to be a paraphenylendiamine or similar substance). The dye caused sores on the head, a spreading rash, swelling, affection of the heart and nerves, and permanent disfiguration. It was admitted by the proprietors that the hair dye had untoward effects in persons whose skin was especially susceptible. It was argued, however, that the dye was accompanied by instructions which stated that a test was necessary before using it; that the plaintiff, though she had read the instructions, ignored the test, and that therefore she was negligent in applying the dye and was alone responsible. The jury awarded her $2,500 plus a further sum agreed on as special damage.

Foot-and-Mouth Disease in Animals in Great Britain Introduced from the Continent

Outbreaks of foot-and-mouth disease in domestic animals have been giving much trouble in recent years. Last month the number of outbreaks was eighteen; in April, ten, and in March, nineteen. In the last ten days Scotland, which had previously been free, became the center of an outbreak, and in connection with this the important discovery was made that it originated in foreign pigs brought for curing to British bacon factories. There have been seven outbreaks in the vicinity of a bacon factory at Carluke, and they were all traced to virulently infected carcasses brought in from Holland and Belgium through Rotterdam. The virus is supposed to have been conveyed by human agency or by sewage. There has been another case of foreign infection through Carlisle, and a shipload including infected carcasses has arrived at Leith. It has been long suspected that foot-and-mouth disease might be brought to this country by foreign meat, and especially offal, which is obviously an extremely dangerous source of infection. For the first time there is absolutely definite and complete evidence. The government has therefore prohibited the importation of carcasses from the continent. The only exceptions from this prohibition are: (*a*) fully cured bacon and ham, lard or rendered fat, cooked or preserved meats or meat essences, and (*b*) hides and skins that have been dried, dry-salted or wet-salted. Wet-salted hides or skins must be accompanied by a certificate to the effect that they have been wet-salted for a period of fourteen days.

International Congress of Surgery

More than 500 surgeons attended the seventh international congress of surgery, which recently convened at Rome.

THE OPENING SESSION

The opening session of the congress was held, April 7, under the chairmanship of Premier Mussolini. After a short address of welcome by the governor of the city, Mussolini reviewed rapidly the history of surgery. It was at the close of the first session that he was wounded in the nose by a shot fired by Miss Gibson. The shot was deflected by Professor Giordano, who seized the hand of the assailant. The bullet, after piercing Mussolini's nose, struck the back of the hand of Professor Alessandri, director of the surgical clinic of Rome, producing a slight contusion.

THE WORK OF THE CONGRESS

The first scientific assembly was held, the afternoon of the same day. The main paper on the first topic, "Radium Treatment of Cancer of the Uterus," was presented by Professor Regaud of Paris. Our statistics, he said, are based on treatment given in 1919 and 1920, since the results must take into account a five-year period of observation. These results show from 15 to 20 per cent of recoveries in all cases without regard to the stage of the disease, or from 40 to 60 per cent recoveries in cases in the primary stage. During the last five years, however, with improved technic, the percentage of recoveries appears to be increasing. Professor Pestalozza of Rome stated that, whenever the tumor can be extirpated, he advised a radical operation, preceded and followed by treatment with radium and roentgen rays. Beuttner is convinced that actinotherapy will continue to increase in importance. Recasens of Madrid explained the therapeutic action of different rays. He emphasized the problem of radium dosage.

The second topic, "The Therapy of Cerebral Tumors," was discussed the afternoon of April 8, the conventionists having spent the morning in clinics and hospitals. Professor Adson of Rochester, Minn., spoke on trigeminal neuralgia, comparing the results of alcohol injections, peripheral nerve excision and radical operation. In addition to his personal statistics on around 300 operations, he referred to several hundred further cases radically treated at the Mayo Clinic. Professor Lozano of Saragossa expressed the conviction that, in spite of the high mortality, extirpation remains the preferred method in the treatment of cerebral tumors. He gave the following statistical figures: an operative mortality of 40 per cent in tumors of the anterior cerebral fossa; 55 per cent in tumors of the posterior fossà; remote cases in which a definite cure resulted amounted to 20 per cent.

The following day (April 9), the third topic was taken up: "Remote Results in the Treatment of Jacksonian Epilepsy." The single paper on the subject was presented by Prof. M. R. Leriche of Strasbourg, who, from his experience with about thirty cases, concluded that jacksonian epilepsy is always associated with a cicatrix caused by a cerebral contusion. According to Leriche, the only true cure consists in excision of the fibroneurogliar cicatrix, which, however, might be influenced by radiotherapy. The speaker emphasized also the rôle of cerebrospinal fluid pressure in the convulsions of jacksonian patients. In the discussion Professor Alessandri of Rome emphasized the need that in operation interventions the normal anatomic planes be reconstructed.

The next congress, to be held in 1929, will convene in Warsaw. Prof. H. Hartmann of Paris was chosen president. A resolution was passed accepting German surgeons as members of the International Surgical Society as soon as

Germany shall have become a member of the League of Nations.

April 10, the last two topics on the program were discussed. The morning was devoted to "Surgery of the Spleen." Papers were presented by Patel of Lyons, N. Leotta of Bari, Papayoannon of Ghesireh, Henschen of St. Gallen, and Cortes Llado of Seville. On the afternoon of this day, the fifth topic was discussed: "Abscesses of the Liver." The first speaker, Prof. M. L. Dominici of Sassari, after dividing the abscesses of the liver into pyogenic and amebic, spoke of the differential diagnosis and of the various forms of treatment. Prof. Paulos Petridis of Alexandria, Egypt, referred to his 538 cases of hepatic abscesses treated in the Greek hospital of Alexandria from 1896 to 1925. He stated that in recent years the number of such morbid types had notably decreased, owing to the use of emetine. In the discussion, Giordano referred to his 140 cases in which puncture of the viscera gave no practical results. Matthiasson of Akureyri referred to the frequency of echinococcus cysts in Iceland.

Statistical Data on Industrial Accidents

During the first eight months of the forty-second year of its existence, the Cassa nazionale di assicurazione has issued 66,864 new industrial accident insurance policies, whereby 824,051 workmen were insured. It has received 123,634 accident claims and has expended 49,039,000 liras in the adjudication of 109,205 cases, 400 of which were death claims and 6,127 were for permanent disability. In the compulsory insurance of agricultural laborers, the *Cassa* has received 34,705 accident claims and has distributed 11,571,000 liras in the adjustment of 26,870 cases, 526 of which were death claims and 2,779 were for permanent disability.

Morbidity and Mortality Among Nurses

Among the regular nursing personnel of the Ospedale maggiore in Milan, during the period 1910-1920, the average annual morbidity was 1.32 per cent among the male nurses and 1.03 per cent among the female nurses, excluding the sisters of charity. The increase in the number of days absence from duty has been considerable and is progressive. A ruling adopted in 1919, to the effect that long absence from work because of tuberculosis would not result in dismissal, has been a major cause of the increase.

Statistics on Psychopaths

According to a census taken in October, 1925, the number of persons confined in institutions for mental disease in all Italy is 59,393, which is 1.5 per thousand of population. This shows an increase of 5,082 patients since the previous census, taken in 1914.

Course in Industrial Hygiene

Under the auspices of the Associazione degli industriali italiani and with the collaboration of the minister of political economy, a course of lectures, to be followed by practical drill, on "Industrial Hygiene and the Prevention of Accidents" will soon be held. This course, which is the first of the kind to be held in Italy, will take up the prevention of industrial accidents, and will be especially for inspectors of industry and labor, though any workmen may take the course.

Coordination of the Antituberculosis Crusade in Latium

According to the plans of the governor of Rome, a general house sanitation campaign will be launched in the city and will be aimed at the homes of the tuberculous in particular; a work colony will be established for tuberculous persons. In addition, there will be coordination of the home visiting service; provision will be made for the children of tuberculous mothers and especially for infants; the public health service will be improved, including the establishment of numerous public baths.

BERLIN

(From Our Regular Correspondent)

May 15, 1926.

Meeting of the German Roentgenologic Society

The meeting of the Deutsche Röntgen-Gesellschaft was held in Berlin, April 11-13, the first main topic being "Is Postoperative Irradiation of Cancer of the Breast Justified?" Jungling of Tübingen suggested that four stages be distinguished: (1) tumor confined to the mammary gland; (2) tumor no longer freely movable toward the skin and the pectoralis muscle; (3) axillary glands all involved, and (4) intraclavicular glands involved. Results of postoperative irradiation therapy, not based on such a classification, have not been easy to evaluate. Statistics on series of cases less than fifty should be disregarded. In the Kiel Clinic, postoperative irradiation of 221 cases has given improved results, whereas in Tübingen, with a series of 447 cases, it has caused no improvement but rather poor results. Rostock and Hamburg report an improvement in cases extending over three years but no improvement (or poor results) in cases extending over five years; prophylactic postoperative irradiation only delayed the recurrences. Heavy doses seem without value for postoperative irradiation. The technic recommended by H. Meyer of Bremen, which consists of fractioned moderate doses, has proved most effective. Ten surgical clinics do and ten do not apply postoperative irradiation. Five clinics use the method only in advanced stages or at the request of the patient. In any event, cancer of the breast should be operated on as radically as possible. Reliance on postoperative irradiation to eliminate remnants of cancer tissue is not well founded. Reported results in stage 1 justify any one in refusing prophylactic postoperative irradiation. Holfelder of Frankfort-on-the-Main pointed out that the effects of after-irradiation were poorer, the heavier the doses administered. That is quite intelligible because, on the one hand, the latent cancer cell (in contradistinction to the fully active cell) cannot be definitely injured by any dose; and, on the other hand, the possibility of an impairment of the defense forces of the organism must be taken into account. A safe norm [illegible] of an erythema dose at intervals of from four to six weeks from eight to ten times in succession. Holfelder does, however, think postoperative irradiation is desirable in especially malignant cancers.

The second topic, "The Roentgenology of the Gallbladder," was treated by O. Strauss of Berlin and Pribram of Berlin. The whole situation has been changed since the Graham method has been introduced. Tetraiodophenolphthalein has proved the best agent, at least as far as intravenous application is concerned. Peroral, duodenal, jejunal and rectal or intravenous applications may be employed. The intravenous infusion has been found superior to all others. The dangers associated with the Graham method have been greatly exaggerated. The deaths so often referred to were the result of an entirely different preparation. The procedure can be regarded as harmless, and there is no objection to ambulant application. It has become routine practice to evacuate the gallbladder by the use of pituitary preparations. Likewise, atropine before the infusion has proved valuable. In intravenous injection, one must be willing to sacrifice time and to infuse slowly, drop by drop, the required agent, dissolved in 40 cc. of distilled water. That requires about fifteen minutes. Pribram announced that he is engaged in the elaboration of a new agent which in its application promises to be simple and which will give good results.

Hanisch of Hamburg, in spite of his success in diagnosis without the Graham procedure, admitted that the Graham procedure is supplanting the older methods more and more.

Schöndube of Frankfort-on-the-Main was able to demonstrate stones in four instances by the Graham method, whereas, with the ordinary method for calculi, their presence had not become known. However, in three other cases the stones could be seen by the ordinary technic, whereas the bladder was not brought into view by the Graham method. Schöndube assumes that a marked secretion of calcium carbonate occurs only when the bladder is closed. Whereas other authors recommend that the roentgenogram be made sixteen hours after the infusion of tetraiodophenolphthalein, Schöndube regards that time as too long. He found that the filling began after the lapse of from three to five hours, and that the optimum was reached in eight hours. To be sure, the observations of the authors and Schöndube's experiences are not comparable without adjustment, since Schöndube does not employ atropine, which paralyzes the motility of the gallbladder and counteracts the effect of the pituitary preparations. In ten cases in which the gallbladders after from five to eight hours were in a good condition to be photographed, Schöndube found no shadows after twelve hours. Five of the patients were pronounced asthenics with cholecystoptosis and presented an unusually marked motility of the gallbladder. Schöndube is an advocate of the intravenous method. He admits, however, that he observed thrombi in 8 per cent of the cases. It is possible that the hemolysis which follows the infusion is the cause of the thrombosis. Rachwalski proposed a new preparation; Gotthart of Munich emphasized the need of caution in patients with exophthalmic goiter. Many were outspoken advocates of the peroral method. The statement that, by means of cholecystography, a correct diagnosis could be reached in from 90 to 100 per cent of the cases was confirmed in the main. The authors held to the view that absence of all roentgen-ray findings occurs in cases of bladder closure.

Holthusen of Hamburg spoke on the "Standardization of Roentgen-Ray Dosage." Glocker of Stuttgart proposed that changes be made in the recommendations of the Deutsche Röntgen-Gesellschaft published in 1913 on the subject of protective measures against roentgen rays. Ernst S. Mayer reported a form of cancer therapy. Fritz reported his observations, made with Posner, to the effect that the glycolysis of tissues, measured by the Warburg method, which requires the exclusion of oxygen, is retarded by the roentgenization of tissue preparations in vitro, whereas irradiation exerted no influence on the respiration of the tissues when that was measurable. The objects examined were the Flexner rat carcinoma, the Jensen rat sarcoma, chicken embryos and the testes of sexually mature rats and mice. At first the investigators did not succeed in confirming in living animals after irradiation of tumors the results obtained after irradiation in vitro. Only when, following the method of Mayer of Vienna, hypertonic glycolysis solution was injected in the animals immediately before the irradiation, did the tumors extirpated immediately after the irradiation, as well as the tumors irradiated in vitro, show any considerable reduction of their glycolysis. Sgalitzer spoke on the roentgen-ray treatment of brain tumors, stating that a glioma, owing to irradiation, had improved to such an extent that the patient could again perform heavy labor. Lorey of Hamburg spoke on bronchography. The ordinary roentgenologic examination had failed in many instances in bronchial diseases, whereas, by filling the bronchi with a contrast medium, excellent results had in most instances been secured. The same thing is true of bronchostenoses and bronchial tumors. The effect of lung collapse in pneumothorax can be studied in excellent fashion by the use of the contrast medium. The method gives also valuable data on the anatomy of the bronchial tree and concerning physiologic questions (peristalsis of the bronchi, etc.).

Correspondence

IODINE IN TUBERCULOSIS

To the Editor:—In discussing "Modern Methods in Diagnosis and Treatment of Pulmonary Tuberculosis" (THE JOURNAL, March 27, p. 973), the reviewer relegates to the commonplace a book that certainly has value, but particularly condemns the use of iodine in the treatment of tuberculosis, at one fell swoop, relegating it to antiquity. I do not believe that any authentic experiments have ever been done to show that iodine breaks down a lung in a tuberculous animal or in man. Except for the report of some guesses on the part of a few men, iodine has not been said to have any harmful effect in this disease. On the other hand, a discussion of the subject by Ragins in the *Bulletin of the Chicago Municipal Tuberculosis Sanitarium* will convince one that iodine may have a place in the treatment of tuberculosis, and that its use certainly has more advocates than antagonists.

E. A. PETERSON, M.D., Denver.

"SENSITIZED BACTERIAL VACCINES"

To the Editor:—In answer to a query regarding sensitized bacterial vaccines (THE JOURNAL, April 24), a statement was made that "sensitized bacterial vaccines are objectionable because they may sensitize the injected person to the proteins in the animal serum with which the bacteria have been treated." Apparently it is assumed that sufficient animal protein must be present in a human dose of the vaccine to cause sensitiveness.

Such vaccines (serobacterins) are sensitized with cattle serum, not horse serum. Also, sensitized bacterial vaccines are not a mixture of serum and vaccine, but the organisms after treatment with the serum are washed with salt solution, recentrifugalized, and finally diluted again in salt solution. The only free serum that could be present is that which clung mechanically to the organisms during the sensitization. The subsequent washing would act as a progressive dilution of this serum, and a calculation of this dilution shows that the greatest amount of serum that could be present in a dose administered to man is 1:1,250,000 cc. This is less than the amount necessary to sensitize a guinea-pig, much less a human being. The only other source of such a suspected sensitization would be the antibodies that are attached to the bacteria. This necessitates the assumption that the antibodies are of a protein nature, and, further, that they are of such a protein nature that would produce sensitiveness. Neither of these suppositions has as yet been proved.

F. M. HUNTOON, M.D., Glenolden, Pa.
Medical Director, H. K. Mulford Company.

TEACHING POSITIONS IN THE PRECLINICAL SCIENCES

To the Editor:—Some years ago the Federation of American Societies for Experimental Biology established a bureau of information, the object of which was to furnish a medium of communication between institutions desiring men to teach in the preclinical sciences and men who are engaged in teaching these sciences, but who desire for some reason or other a change of location. This bureau has been functioning for some years and has been instrumental in placing a considerable number of men in the departments of physiology, biologic chemistry, pharmacology and pathology in the various medical schools in the country.

At present there are available in the files of the director of the bureau the names of a considerable number of men who are anxious to secure positions as teachers in the branches named above. On the other hand, it is rather striking that very few medical schools are making inquiries regarding such men. This may, of course, be because there are no vacancies. On the other hand, it is more likely that the officials in charge of these schools have overlooked the existence of this bureau.

I will be very glad at any time to furnish any information to administrative officers of the schools, or to aid in any way in placing men who have registered with the bureau.

C. W. Edmunds, M.D.,
Director of the Information Bureau.
University of Michigan,
Ann Arbor, Mich.

Queries and Minor Notes

MILK FROM TUBERCULOUS COWS

To the Editor.—I am enclosing a clipping from the *Rural New Yorker* and would be glad to have your opinion respecting the safety of milk from tuberculous cows.

Is it true that human tuberculosis is on the decline? If so, is there, or is there not, a corresponding increase in pneumonia and other respiratory diseases, suggesting that infantile infection with tuberculosis may terminate later in these other forms (through increased susceptibility)?

The statement was recently made in the Cleveland *Plain Dealer* that tuberculosis is now several times more prevalent than formerly among Cleveland school children. In perhaps no other region has there been a more persistent fight by dairymen against the control of bovine tuberculosis than in the region supplying Cleveland with milk. It is true, however, that the population of Cleveland consists very largely of foreigners of the more ignorant classes.

My own observations, during a long life spent on the Ohio farm or in close touch with it, is that bovine tuberculosis is a comparatively new disease in Ohio.

The herd of the Ohio Experiment Station was infected with tuberculosis thirty years ago. We cut out the cancer, at a heavy cost, it is true; but, regarded from the pecuniary standpoint alone, it was a most profitable investment, for by following it with thorough disinfection and the annual use of the tuberculin test, a healthy herd has since been maintained.

Charles E. Thorne, Wooster, Ohio.

Answer.—The mortality from human tuberculosis is definitely on the decline in most countries. In the United States it is less than half of what it was at the opening of the present century. There has not been an increase in pneumonia or other respiratory disease, except during the influenza epidemic, nor is there any evidence that infantile infection with tuberculosis may terminate in these diseases by increasing susceptibility. The mortality for pneumonia (all forms) in the registered area of the United States was 180.5 per hundred thousand in 1900 and 137.3 in 1920. Certain diseases, notably cancer and chronic diseases of the vascular system and kidneys, have increased, partly, without question, because the lowering of mortality from tuberculosis has permitted a larger proportion of the population to live to the age when these diseases are more common.

There is no proof that tuberculosis is more common than formerly among Cleveland school children. The commissioner of health of Cleveland suggests that this impression has become prevalent because of the increased number of reports of tuberculosis resulting from the Cleveland method, recently adopted, of issuing working permits to children of school age only on the basis of physical examination. These examinations have resulted in the recognition of many cases of mild tuberculosis that would otherwise have been undetected. The mortality from tuberculosis in Cleveland for the age period 5-19 years, which includes the school years, has been as follows for the last five years: 1921, 125; 1922, 84; 1923, 98; 1924, 92, and 1925, 86 (figures given by the commissioner of health). In view of the increased population, these figures indicated a decided decrease in the mortality rate.

No competent observer in recent years has seriously questioned the infectiousness of bovine type tubercle bacilli for man. While only a small amount of adult tuberculosis appears to be of bovine origin, about one quarter of the extrapulmonary tuberculosis of childhood, as shown by several extended investigations, is of bovine origin. Several of the statements in the letters printed in the clipping from the *Rural New Yorker* are correct in fact but wrong in implication. It is true that many cattle giving positive tuberculin reactions may live out their natural length of life in apparent health. Nevertheless, such cattle have been infected with tuberculosis. The severity of infection is ordinarily not determined by the tuberculin test. Although only about 25 per cent of reactors have been found on investigation to eliminate tubercle bacilli with the milk, there is no method known at present of ascertaining which reactors are capable, and which are not of contaminating their milk with tubercle bacilli, and therefore all infected cattle are to be considered potential spreaders of tuberculosis.

Statistics that take into account only the mortality from tuberculosis and ignore the disability are apt to be misleading. It is true, as stated in two of the letters printed in the *Rural New Yorker*, that certain studies have failed to show a direct correspondence between human and bovine tuberculosis in certain localities. In addition to the Swedish studies cited, Boquet (*Rev. d. tuberc.*, December, 1921, p. 485) has made a similar report on certain regions in Italy, and Cummins (*Public Health* 35:251, 1922) has noted that the disease tends to be severe in localities in England where the herds are free from tuberculosis. Cummins thinks that some immunity against the human type infection may be conferred by early mild bovine infection, but states that this is no argument against the eradication of bovine tuberculosis, as infection of this type leads in many instances to serious disease. It has been asserted that almost 25 per cent of the fatal tuberculosis of childhood in England can be attributed to bovine tuberculosis, and this does not take into account the nonfatal tuberculosis of bones, joints and lymph nodes leading to some permanent disability.

COMPLICATIONS OF ORCHITIS

To the Editor.—In September and October, 1925, I attended, during a small epidemic of mumps, two cases with complications of orchitis. The orchitis was definite on both sides in one case. In the other case one side was affected, but the other side was doubtful. Both patients were healthy men aged about 20. Jan. 2, 1926, both had swelling of the mammae. The man with the double orchitis had a big swelling of both breasts, not painful, firm and regular of consistency, no redness, no local glandular swelling in the axilla. In March, the swelling was going down slowly. The breasts were then 2½ inches in diameter. Is this swelling of the breast a well known after effect of double orchitis in mumps? I should like to know some more about it. In November, 1925, the semen contained live spermatozoa, but these could have come from the vesicles. There are cases reported of male persons having secreting breasts.

L. J. TeGroen, M.D., Pretoria, British South Africa.

Answer.—The breasts may become swollen and hard, also painful, in much the same way as the testes and the ovaries may be involved in mumps, and this process may develop in males as well as in females. Mastitis has been observed to develop in the course of mumps even in young boys. This involvement of the breasts in mumps seems to be known well enough, but it does not appear to be frequent and it does not seem to have attracted as much attention as other complications.

INDUSTRIAL DERMATITIS

To the Editor.—We use as a back sizing for our axminster rugs a mixture made by dissolving in 120 gallons of water 100 pounds of tapioca flour, 60 pounds of British gum and one half pound of caustic soda, with 1.225 specific gravity. The "British gum" is bought by us and is probably a mixture of various starches and dextrin. Recently, severe cases of rash or eczema have appeared on the hands and arms of five or six of the men who handle the rugs after they have been back sized. Not all of the men so engaged, however, have contracted this rash. We are wondering whether, from previous similar cases that may have come to your attention, you can advise us as to the probable cause of this rash. That is, have you reason to believe that the malady is traceable to possible impurities in the sizing, particularly in the "British gum"? Could such impurities be determined by a chemical analysis? We are writing to you in the belief that you keep a record of cases of industrial diseases and that you may have on record in your files something similar to this case.

Walton C. Forstall, Amsterdam, N. Y.

Answer.—The mixture used for back-sizing the rugs may well be a source of dermatitis. Medical literature seems to show no reference to irritation produced by tapioca flour, but dermatitis developing from wheat flour is generally conceded to occur, and it is entirely probable that the tapioca flour might produce a similar condition. "British gum" is dextrin and may well be the irritating factor, as dermatitis among those handling sugars is not at all uncommon. Skin tests of the susceptible persons may be tried, and in that way the specific irritant might be determined.

District of Columbia April Examination

Dr. Edgar P. Copeland, secretary of the Board of Medical Supervisors of District of Columbia, reports the oral and written examination held at Washington, April 13-15, 1926. The examination covered 16 subjects and included 80 questions. An average of 75 per cent was required to pass. Of the 12 candidates examined, 11 passed and 1 failed. Seven candidates were licensed by reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
George Washington University Medical School	(1925)	86.4
Howard University School of Medicine	(1925)	75.8, 76.6, 82.5
Loyola University School of Medicine	(1919)	77.8
University of Kansas School of Medicine	(1920)	83.8
Tulane University of Louisiana School of Medicine	(1907)	77.6
John A. Creighton Medical College	(1919)	87.3

Woman's Medical College of Pennsylvania	(1906)	Penna.
University of Vermont College of Medicine	(1903), (1922)	Vermont

Book Notices

Caesarean Section. With a Table of 120 Cases. By Herbert R. Spencer, M.D., B.S., F.R.C.P., Consulting Obstetric Physician to University College Hospital. Cloth. Price, $2.75. Pp. 71, with 5 illustrations. New York: William Wood & Co., 1925.

In this interesting book the author reviews his entire experience with cesarean section. Since 1892 he has performed 120 of these operations, the records of which are tabulated and critically analyzed. The number of operations is not greater because at the University College Hospital, where 110 of the operations were performed, premature labor is induced three and a half times as often as cesarean section is done for contracted pelves. In this hospital the incidence of cesarean section is 5.5 per thousand. Indications for the operation were noted as follows: contracted pelvis, ninety-eight, with two deaths; myoma, nine, with one death; pelvic enchondroma, one, which ended fatally; accidental hemorrhage, four; vaginal and uterine scars, three; ovarian tumors, three; ventrifixation, one; cancer of the cervix, one, and placenta praevia, one. Only thirty-five patients were in labor at the time of the operation because the author believes that the best time to operate is before labor has begun. Many operators, however, feel that the most favorable time is after the patient has had some labor pains. All of Spencer's operations were of the classic type, and in all the cases the uterine incision was sutured with phenolized floss silk. In the United States nearly all operators prefer catgut to silk for closure of the uterus. The maternal mortality was 3.3 per cent. The immediate fetal death rate was 4.1 per cent, but the entire fetal mortality was 10 per cent. At present the patients are given chloroform until the baby is delivered, and after that ether. The author feels that chloroform is much less dangerous to the babies than ether. Although Spencer has never performed a cervical cesarean section, he condemns this type of operation. While some of his objections apply to the extraperitoneal cervical operation, they do not hold good for the transperitoneal operation. For example, Spencer mentions that after the cervical operation adhesions are troublesome, and during the operation injury to the bladder and ureter frequently occur. There is also an insinuation concerning rupture of the cervical scar. To date there have been only ten ruptures of the lower uterine segment following transperitoneal cervical cesarean section. The total number of these operations which have been performed all over the world is unknown, but 3,600 have been reported in the literature, and, if we use this number alone as a basis, the incidence of rupture is 0.28 per cent, as compared with 4 per cent for the classic operation, reported by Holland. Adhesions are very uncommon after the transperitoneal operation even in the cases in which more than one operation have been performed. While injuries to the bladder and ureter occur during the extraperitoneal operation, they are practically unknown in the transperitoneal. Spencer is correct when he says that the cervical operation consumes more time. However, the advantages of the new operation outweigh the disadvantage of time, and if the operation is performed under local anesthesia, the time element in most of the cases is not important. Spencer believes that cesarean section need rarely be done for eclampsia, antepartum hemorrhage and advanced age of the patient associated with myoma or malpresentation, and should not be employed in cases of heart disease.

Diagnostische und therapeutische Irrtümer und deren Verhütung Chirurgie. Herausgegeben von Prof. Dr. J. Schwalbe, Geh. San.-Rat *in* Berlin. *Siebentes Heft.* Verletzungen und chirurgische Krankheiten der Mund- und Rachenhöhle, des Halses einschl. der Speicheldrüsen, der Speiseröhre, des Kehlkopfes und der Trachea. Von Prof. Dr. Paul Clairmont, Vorstand der chirurgischen Klinik in Zurich. Paper. Price, 8.10 marks. Pp. 188, with 97 illustrations. Leipsic: Georg Thieme, 1926.

This volume, on the injuries and surgical diseases of the mouth, pharynx and neck together with the salivary glands, esophagus, larynx and trachea, forms the seventh section of the division of surgery, and is written by Professor Clairmont of the surgical clinic in Zurich. Many practical points with reference to the proper diagnosis and th errors, as well as the various complications involving the parts under discussion, are given. Altogether, this small volume presents in a readable and intelligible manner many items of great practical importance to students and surgeons interested in the upper part of the respiratory and digestive tracts.

Physiotherapy. Theory and Clinical Application. By Harry Eaton Stewart, M.D., Attending Specialist in Physiotherapy, U. S. Marine Hospitals, N. Y. Cloth. Price, $7.50. Pp. 351, with 66 illustrations. New York: Paul B. Hoeber, Inc., 1925.

This is a brief outline of physical therapeutic methods based largely on the author's experience in the government rehabilitation service. The description of the apparatus is simple, and the suggestions as to the tehcnic of application are easily followed. The author is unfortunately uncritical in his consideration of the available literature, accepting almost any writer on the subject as an authority, and without reference as to whether or not his work may have been carefully controlled. The tone of the book is highly optimistic, and the therapeutic considerations regularly disregard well established methods in order to recommend unestablished physical therapeutic measures. It is perhaps unfortunate that this field of therapeutics advances by the costly trial and error methods of empiricism, rather than by the more careful but somewhat less renumerative methods of scientific laboratory and clinical investigation.

Artificial Sunlight and Its Therapeutic Uses. By Francis Howard Humphris, M.D., F.R.C.P., M.R.C.S., Hon. Consulting X-Ray Physician to the American Hospital in London. Second edition. Cloth. Price, $2.75. Pp. 203, with 15 illustrations. New York: Oxford University Press, 1925.

Current interest and enthusiasm for heliotherapy in the treatment of disease have necessitated the prompt appearance of the second edition of this book. It is a monograph in beautifully printed form and, in general, conservative. Unfortunately, Dr. Humphris, like most other authors who specialize in one method of treatment, is inclined to overemphasize that method to the disadvantage of long established and more certain methods.

Handbuch der speziellen pathologischen Anatomie und Histologie. Herausgegeben von F. Henke und O. Lubarsch. Zwölfter Band. Gehörorgan. Bearbeitet von A. Eckert, M. Koch, W. Lange, H. Marx, H. G. Runge, O. Steurer und K. Wittmaack. Paper. Price, 84 marks. Pp. 802, with 640 illustrations. Berlin: Julius Springer, 1926.

This volume, on the ear, forms a section of the large handbook of special pathology, anatomy and histology. The first section deals with the technic of the pathologic and anatomic examination. The next subject, the inflammatory processes of the ear, is dealt with by Wittmaack. The latter has also written the third section, on the development of intracranial and septicopyemic complications, as well as the fourth section, on regressive, degenerative and dystrophic processes in the ear. The next section, on malformation of the ear, is by Marx. Runge has written the eighth section, on the relation between the pathologic findings to the function of the ear. The final, or ninth, chapter deals with foreign bodies and animal parasites in the ear, and is written by Max Koch. Complete bibliographies are appended to each section, and the whole work is an excellent exposition of the subject it presents.

Everyday Meals for Invalids. A Collection of Tiny Recipes, Tasty and Nourishing, for Every Day in the Year. By May Tremel. Cloth. Price, $1.25. Pp. 188. New York: Greenberg, Publisher, Inc.

This is essentially a collection of recipes planned to provide enough for one person for one meal and to fill the usual medical wants of nonsolid diet, very light diet, light diet, and convalescent diet. The suggestions should be helpful to those charged with the care of an invalid in the home.

William Cadogan [His Essay on Gout]. By John Ruhräh, M.D., Professor of Diseases of Children, University of Maryland. Cloth. Price, $1.50. Pp. 114, with 1 illustration. New York: Paul B. Hoeber, Inc., 1925.

This is a reprint of an essay originally published in the *Annals of Medical History*. The unusual original article by Cadogan, which attracted wide attention when first printed in 1771, and a poem which circulated about the town at that time supplement Ruhräh's introduction.

History of Medicine. By Dr. Max Neuburger, Professor of Medical History in the University of Vienna. Translated by Ernest Playfair, M.B., M.R.C.P. In two volumes. Vol. II. Part I. Paper. Price, $2.25. Pp. 135. New York: Oxford University Press, 1925.

The first volume of Neuburger's History of Medicine has been before the medical public for many years, a monumental work which has established a standard that is at once the admiration and the despair of other medical historians. Unfortunately, the second volume has repeatedly been delayed by many uncontrollable conditions, including, of course, the Great War. The publishers now present part one of volume II, including chapters on medieval medicine, Arabic influence on Western medicine, medicine in the later middle ages, and a historical survey of medieval literature. The publisher also announces that the remaining parts of the English edition will appear "as and when the German original is published."

A General Textbook of Entomology. Including the Anatomy, Physiology, Development and Classification of Insects. By A. D. Imms, M.A., D.Sc., Chief Entomologist, Rothamsted Experimental Station, Harpenden. Cloth. Price, $12. Pp. 698, with 604 illustrations. New York: E. P. Dutton & Co.

This is a textbook planned distinctly for the specialist rather than for the physician who is interested primarily in insect transmission of disease. The book is well printed and illustrated, and supplied with good bibliographies.

Books Received

Basis of Compensation for Injury to Vision

(Alessandro Petrillo Co. v. Marioni (Del.), 131 Atl. R. 164)

The Superior Court of Delaware holds that, a workman having sustained an injury to his left eye which resulted in an 80 per cent loss of vision, in computing an award for his fractional loss of vision, such award should be based on the percentage of the loss of vision without the use of glasses. It might be true that an artificial instrumentality, such as glasses or a corrective lens, might subsequently be used, by virtue of which the loss of vision might be reduced from 80 per cent to 10 per cent during the time such glasses were actually in use; but the loss suffered by the injury would remain the same, which was the compensable basis. The very fact that artificial instrumentalities such as glasses, braces and artificial limbs are necessary to be used is in itself evidence of the permanence of the injury, but the use of the mechanism itself, although it may allow a member to function with entire normality, cannot obliterate the effect of the accident causing the injury. A number of cases were cited from the jurisdictions of New York, Pennsylvania and Michigan as having arrived at different conclusions from the one herein reached. It may be sufficient to suggest that these cases were determined on their particular statutory enactments. Most or all seemed to be founded on statutes based on the theory that compensation was payable only in cases such as the present one when the accident led to loss of earning power. The workmen's compensation act of Delaware makes a permanent injury to an eye compensable regardless of the earning power of the injured employee after the injury, and this court is of the opinion that the action of the industrial board in basing the award in this case on the loss of vision without the use of a corrective lens should be affirmed.

Payments by Employer for Medical Services

(Johnson et al. v. J. P. Taylor Co. (Ky.), 278 S. W. R. 169)

The Court of Appeals of Kentucky says that in this proceeding under the workmen's compensation act the compensation board awarded the claimant compensation for a permanent partial disability and in addition allowed him $100 for medical services. But the Kentucky statute allows only a maximum of $100 for medical services, and the testimony in this case showed that the employer had voluntarily paid for at least some of the medical services rendered to its injured employee—the claimant. The compensation board took no cognizance of those payments, but allowed the full maximum sum of $100, as just stated. The board should have credited that sum with whatever amount the employer had paid, and awarded only the difference. It should therefore correct its award in this particular.

Duty of Employer Knowing Employee to Be an Epileptic

(Monteith v. Manchester Rendering Co. (N. H.), 131 Atl. R. 440)

The Supreme Court of New Hampshire, in overruling exceptions to a charge to the jury in this action in which there was a verdict for the plaintiff, says that the plaintiff was an epileptic, and the defendant excepted to an instruction that its knowledge of the plaintiff's disease was a circumstance in the light of which its conduct in furnishing a place for him to work was to be judged. The defendant's knowledge of the plaintiff's condition entitled him to special protection so far as due care would give it to him, and the instruction was correct in its application to an injury sustained when the plaintiff had an epileptic attack. It might be conceded that the instruction was given too broadly in its general application regardless of the plaintiff's having or not having an attack when hurt, since the defendant owed him no duty of special protection except as related to an attack. In the absence of an attack, the breach of duty to guard against it could not be made a ground of liability. Causal connection between such breach and the injury would be missing. But the exception to the instruction did not present that feature of it for consideration; that is, that the instruction should be limited to the situation of the plaintiff's having an attack when hurt.

Health Laws May Impose Heavy Financial Burdens

(Chicago & N. W. Ry. Co. v. Railroad Commission (Wis.), 205 N. W. R. 932)

The Supreme Court of Wisconsin, in affirming a judgment that affirmed an order of the railroad commission made pursuant to a statute of the state requiring railroad companies operating in the state of Wisconsin to equip their locomotives with cab curtains of a prescribed protective efficiency, says that the court does not think that there is anything in the contention that the law or the order imposes an undue burden on interstate commerce. If the court is correct, it is a law which the state has plenary power to pass in the interest of the public health. As a rule, such laws impose a burden on some one, but it is a burden that must be borne for the public good. A health law is not invalid because compliance with it may carry heavy financial burdens. If the state had power to pass this law, railroad companies cannot refuse compliance therewith because of the burdens imposed. If the validity of the law depends on the reasonableness of the burden laid on interstate commerce, then all circumstances are to be taken into consideration, and perhaps the conclusion reached becomes more a matter of human judgment than fixed rules or principles.

Compensation for Services of Family Physician

(Succession of Bouziga (La.), 106 So. R. 328)

The Supreme Court of Louisiana says that the final accounting of the administration in the succession of the estate of Mrs. Bouziga was opposed by a physician who alleged that he was a privileged creditor of the succession in the sum of $5,000, with legal interest thereon from Jan. 1, 1924, for professional services rendered Mrs. Bouziga from Jan. 30, 1923, until her death, Dec. 27, 1923. The evidence disclosed that Mrs. Bouziga, who was 77 years of age when she died, was stricken with a cerebral hemorrhage on or about Jan. 30, 1923, and that this physician was called in to treat her. At first her condition improved. Later she developed Bright's disease, and a few days afterward grippal pneumonia. Several weeks after that she developed erysipelas, and, in her declining condition, and at her advanced age, developed senile gangrene and infectious vesicles, which had to be ruptured. She also suffered from incontinence of urine and feces. She left an estate valued at a little over $27,000. Her income was about $100 a month.

The number of visits paid by a physician to his patient, during a protracted illness, is a factor in determining the compensation to which he is entitled. The number of visits paid by this physician to Mrs. Bouziga during the eleven months' period that he attended her was in dispute. The trial judge, after considering the evidence, fixed the number at 300, and the examination of the record by this court led it to the conclusion that there was no reason to disturb his finding in that respect. The services rendered by the physician were those of a family physician. The expert evidence offered to show their value was conflicting. The trial court found that he was entitled to $1,500, but the supreme court's appreciation of the evidence leads it to the conclusion that this was excessive. After considering the number of visits made by the physician, the nature of the maladies from which Mrs. Bouziga suffered, and her means to pay, all of which should be taken into consideration, the opinion of the supreme court is that the evidence justified the conclusion that the physician was entitled to $1,000 and no more, and that the judgment for $1,500 should be reduced accordingly. Wherefore it is ordered that the judgment be amended by reducing the amount allowed from $1,500 to $1,000, and, in all other respects, including the allowance of interest and the recognition of the privilege prayed for, that it be affirmed; the costs of this appeal to be paid by the physician. Rehearing denied.

(Continued from page 1937)

Cirrhosis of the Liver Resulting from Acute Yellow Atrophy

Drs. Joseph H. Pratt, Boston, and Alfred Stengel, Philadelphia: We have found twelve cases among 5,000 of toxic cirrhosis. Our ideas of acute yellow atrophy should be revised. Many cases present the picture of catarrhal jaundice, but are really acute yellow atrophy in which recovery occurs. The textbook description really applies to the severe fatal case.

DISCUSSION

Dr. Jonathan Meakins, Montreal: In Edinburgh the alcoholic type of cirrhosis of the liver is practically unknown. I did not see one case during five years in Edinburgh with this diagnosis, but one woman of 50 was admitted to the Royal Infirmary for some acute condition associated with jaundice. There were leucine and tyrosine crystals in the urine. She had an acute infection in the throat, large abscesses, but was not syphilitic. The jaundice persisted in a mild form. Finally, the woman returned with a severe, acute exacerbation of the jaundice which was very deep. She died and the postmortem showed an acute exacerbation of the necrosis superimposed on previous infection. There was another case, a man of 30, with intense jaundice and great prostration. He had apparently a case of acute yellow atrophy, with leucine and tyrosine in the urine. He recovered with good health, and returned four years later with all the symptoms of acute portal obstruction, from which he died. Necropsy showed a definite cirrhosis of the liver. I was interested to find how often cirrhosis of the liver occurred in Edinburgh, when, according to the records, there are very few cases.

Dr. Alfred Stengel, Philadelphia: Our notions of acute yellow atrophy require fundamental revision. We are dealing with an entity that attaches itself to a number of underlying states. For instance, patients with chronic liver disease frequently die of acute yellow atrophy. We can show that it is acute catarrhal jaundice recognized by all strict criteria, and sometimes terminates as acute yellow atrophy. Acute yellow atrophy is a misnomer when recorded as a fatal disease, but it may be subacute or it may lead to recovery with replacement of cirrhosis and cirrhotic states. It seems rather peculiar that in proving recovery of patients with acute yellow atrophy we should prove it by the few fatal cases, but the recovery refers to previous states. Oomherr said it should be called acute red atrophy of the liver, the liver was so red at operation. Another objection to the term is that it is not entirely an acute disease but comes in acute attacks.

Hyperthyroidism and Diabetes

Dr. Russell M. Wilder, Rochester, Minn.: Patients with hyperthyroidism, even with a trace of sugar in the urine, respond to the glucose test meal by a rise in the respiratory quotient; therefore these patients are not diabetic. When we speak of derangement of carbohydrate metabolism in hyperthyroidism, in cases with true diabetes associated with hyperthyroidism, we are dealing with very rare cases, only nine having been found among 1,800 cases. In a study of 2,300 cases, I found thirteen cases of diabetes. This figure was not high enough to warrant the assumption that the thyroid plays a rôle in the etiology of diabetes. However, when the patient has diabetes, the complication of hyperthyroidism aggravates it and increases the insulin requirement. Iodine acts very favorably on the tolerance of the diabetic patient, and thyroidectomy, which reduces the metabolic rate, acts favorably in such complicated cases. Hyperthyroidism, which causes rise in metabolism, is a very dangerous complication. Drugs that lower the metabolism in hyperthyroidism have a good effect on the tolerance of the patient with diabetes. The only exception to this rule is exercise, which seems to have the reverse effect. These observations deserve especial attention, the most significant thing being the influence of iodine in diabetes. This drug improves tolerance by lowering the metabolic rate, and when it does not lower the metabolic rate it has no influence. Therefore the body requires a given quantum of glucose, but it requires more insulin when the cell is stimulated by hyperthyroidism, which causes it to convert energy at a more rapid rate. The patient with no diabetes has more than enough insulin to meet excessive demands, but the patient with diabetes has not enough insulin for excess demands.

DISCUSSION

Dr. Henry A. Christian, Boston: The explanation given by Dr. Wilder is probably correct. A hyperthyroid condition overdrives the circulation, and if we carry out therapeusis for circulatory disease we undertake to give complete rest. Perhaps the ideal rest is in the condition of hypothyroidism, so that if we reduce thyroid efficiency we increase the potential efficiency of the circulation. If the patient has myxedema and also organic circulatory disturbance, we are confronted with a problem of curing the myxedema without harming the circulation. We sometimes have the problem of myxedema with anemia, combined with a myocardial lesion, which seems to be the effect of the myxedema. It is necessary to improve the anemia by improving the myocardial condition by giving thyroid, but we are limited by the response in the already injured heart muscle. That relation between circulatory disturbance and thyroidism parallels closely diabetes with hyperthyroidism or hypothyroidism.

Dr. Elliott P. Joslin, Boston: When a diabetic patient has symptoms of hyperthyroidism, one should relieve the patient of the cause of the symptoms. Diabetic patients with hyperthyroidism should be operated on. The greatest emergency is the danger of overfeeding. Injudicious feeding, fever or any other cause that increases metabolism, such as hyperthyroidism, must be guarded against.

Dr. W. M. Boothby, Rochester, Minn.: Another group of patients who are very important are those with diabetic coma, who do not respond to the usual dosage of insulin, and have no infection. In such cases there may be a combination of hyperthyroidism and diabetic coma. We should be on guard for cases of diabetes combined with adenomatous goiter with hyperthyroidism. Probably it would not be worth while to make a differential diagnosis. It would be sufficient to establish that there was hyperthyroid activity, and to give large doses of compound solution of iodine, approximating 100 minims (6 cc.) in the first twenty-four hours.

Dr. Russell M. Wilder, Rochester, Minn.: We have given thyroxin to a well controlled patient receiving insulin, with severe diabetes. We mixed the thyroxin with the insulin. We let it stand for twenty-four hours and then injected it. If the old theories were right, we should see immediate effect, but we got response after thirty-six hours. When the basal metabolic rate went up, we have let it stand seventy-two hours. In our observations on hyperthyroidism we found that when the liver is empty of glycogen it has an important clinical bearing. Patients with hyperthyroidism very frequently have livers that are poor in glycogen; and, being poor in glycogen, doses of insulin produced very severe hypoglycemia. One case occurred in which the surgeon did not understand what the collapse of the patient was due to. The surgeons had taken the blood pressure and were surprised to find that it was high. When glucose was injected, the patient recovered from collapse and the blood pressure fell. There can be a hyperpyesia in hypoglycemia. Hypoglycemia occurs in a patient with collapse.

Abdominal Puncture in Diagnosis of Acute Intraperitoneal Disease.—Exploratory abdominal puncture is said by Neuhof and Cohen to be a simple, safe, and valuable aid in the diagnosis of obscure acute intra-abdominal disease. It serves to establish the diagnosis of a traumatic or inflammatory intraperitoneal lesion in some cases in which the diagnosis cannot otherwise be made. In other instances, abdominal puncture offers conclusive information as to the source and nature of a peritonitis, and thus aids directly in arriving at the therapeutic indication as well as the prognosis. In the peritonitis group, abdominal puncture is of especial value in establishing the diagnosis of the pneumococcus and streptococcus infections. Abdominal puncture is contraindicated in any subacute or chronic intra-abdominal disease in which a loop of intestine may be fixed. A negative abdominal puncture does not exclude the presence of fluid and should therefore never be interpreted as a contraindication to operation in suspected peritonitis or traumatic visceral lesions. Abdominal puncture should be employed as an aid to diagnosis in every obscure acute intraperitoneal lesion for which operation may be indicated.

Local and General Anesthesia in Laparotomy.—One hundred consecutive upper abdominal operations have been studied. Fifty of these were performed under ether and fifty under local, or local and gas anesthesia. All operations were performed by one surgeon, in the same hospital, with practically no changes in the surgical staff or the floor nurses. General anesthesia was induced by the inhalation of nitrous oxide and oxygen and continued with ether given by the open or drop method, an Esmarch inhaler being used. The local anesthesias were induced by infiltration of the anterior abdominal wall, followed by anterior splanchnic block. The solution used was a 0.5 per cent solution of procaine in 0.6 per cent sodium chloride, with 9 drops of epinephrine chloride added to each 100 cc. An average of only eight minutes more was required for each operation under local, than for each of the fifty under ether anesthesia. The average temperature for the first week after operation was below 99 F. in local cases and above 99 F. in ether cases. The average stay in the hospital after operation was three days less for the cases under local anesthesia. Of the local anesthetic patients only eighteen vomited, while thirty-three of the ether patients vomited. Also, in the latter, vomiting was more marked and more persistent. Only nineteen of those having a local anesthetic against thirty of the ether patients suffered gas pains. Severe shock was experienced only once in this series, and mild shock four times. This occurred each time after ether anesthesia. There was no surgical shock after anesthesia by local injections. Bronchitis was encountered in eleven patients taking ether and in three after local anesthesia. There was one pneumonia case. This patient, who was 59 years old, had an acutely diseased gallbladder and bilateral pyelitis. Operation was under local anesthesia and was successful from the operative standpoint. The patient died eight days after operation—the only death of this series. There was no hernia or phlebitis.

Aseptic Intestinal Anastomosis.—It was recently observed that if the walls of an empty loop of bowel are approximated and strongly crushed in a clamp, they will adhere to each other quite firmly and the intestinal lumen remain occluded after the clamp has been removed. This fact has been utilized by Scarff in the development of a simple technic for aseptic end-to-end anastomosis of the intestine.

Tuberculosis of Cecum.—Larimore and Fisher report five cases of tuberculosis of the cecum with involvement of the lungs, in which the cecum was resected. There was one operative mortality; in general, the convalescence has been uneventful and satisfactory.

Dead Fascia Grafts in Herniotomy.—Experiments made by Koontz show that grafts of dead fascia, preserved in alcohol, when transplanted among living connective tissues, remain intact and unite with the tissue of the host. After a period of a few months, it is impossible to distinguish the living from the "dead." The living and "dead" are likewise indistinguishable microscopically. The suturing together of the internal oblique muscle and Poupart's ligament with strips of dead fascia in the dog results in the firmest type of fibrous union. Large, experimentally produced, ventral hernias in the dog can be successfully repaired by the use of large grafts of dead fascia. Dead fascia grafts may be homogenous or heterogenous.

Pathology and Roentgen-Ray Diagnosis of Periapical Tooth Infection. K. H. Thoma, Boston.—p. 768.
Chronic Fatigue in Schoolchild: Psychophysiologic Study. M. Seham, Minneapolis.—p. 770.

Reticulated Red Cells.—An analysis of the red blood cells in forty-nine cases of pernicious anemia is presented by Dameshek. He regards the reticulate count of the red cells as a true index of bone marrow activity. Before and at the beginning of any remission or permanent rise in red count, the reticulate count surpasses 6 per cent; as the culmination of the rise is reached, it gradually falls to normal (from 0.5 to 1 per cent). With bone marrow aplasia, the reticulate count is extremely low, practically nil. There is no better index to prognosis in pernicious anemia than the count of the reticulated cells. Although these are frequently increased, and an elevation up to 5 per cent represents probably regeneration going on in the face of greater destruction—a sudden rise in count to more than 6 per cent presages a coming remission, overbalancing destructive forces. Very grave are the continued low counts that bespeak forthcoming death.

Cirrhosis of the Liver Resulting from Acute Yellow Atrophy

Drs. Joseph H. Pratt, Boston, and Alfred Stengel, Philadelphia: We have found twelve cases among 5,000 of toxic cirrhosis. Our ideas of acute yellow atrophy should be revised. Many cases present the picture of catarrhal jaundice, but are really acute yellow atrophy in which recovery occurs. The textbook description really applies to the severe fatal case.

DISCUSSION

Dr. Jonathan Meakins, Montreal: In Edinburgh the alcoholic type of cirrhosis of the liver is practically unknown. I did not see one case during five years in Edinburgh with this diagnosis, but one woman of 50 was admitted to the Royal Infirmary for some acute condition associated with jaundice. There were leucine and tyrosine crystals in the urine. She had an acute infection in the throat, large abscesses, but was not syphilitic. The jaundice persisted in a mild form. Finally, the woman returned with a severe, acute exacerbation of the jaundice which was very deep. She died and the postmortem showed an acute exacerbation of the necrosis superimposed on previous infection. There was another case, a man of 30, with intense jaundice and great prostration. He had apparently a case of acute yellow atrophy, with leucine and tyrosine in the urine. He recovered with good health, and returned four years later with all the symptoms of acute portal obstruction, from which he died. Necropsy showed a definite cirrhosis of the liver. I was interested to find how often cirrhosis of the liver occurred in Edinburgh, when, according to the records, there are very few cases.

Dr. Alfred Stengel, Philadelphia: Our notions of acute yellow atrophy require fundamental revision. We are dealing with an entity that attaches itself to a number of underlying states. For instance, patients with chronic liver disease frequently die of acute yellow atrophy. We can show that it is acute catarrhal jaundice recognized by all strict criteria, and sometimes terminates as acute yellow atrophy. Acute yellow atrophy is a misnomer when recorded as a fatal disease, but it may be subacute or it may lead to recovery with replacement of cirrhosis and cirrhotic states. It seems rather peculiar that in proving recovery of patients with acute yellow atrophy we should prove it by the few fatal cases, but the recovery refers to previous states. Oomherr said it should be called acute red atrophy of the liver, the liver was so red at operation. Another objection to the term is that it is not entirely an acute disease but comes in acute attacks.

Hyperthyroidism and Diabetes

Dr. Russell M. Wilder, Rochester, Minn.: Patients with hyperthyroidism, even with a trace of sugar in the urine, respond to the glucose test meal by a rise in the respiratory quotient; therefore these patients are not diabetic. When we speak of derangement of carbohydrate metabolism in hyperthyroidism, in cases with true diabetes associated with hyperthyroidism, we are dealing with very rare cases, only nine having been found among 1,800 cases. In a study of 2,300 cases, I found thirteen cases of diabetes. This figure was not high enough to warrant the assumption that the thyroid plays a rôle in the etiology of diabetes. However, when the patient has diabetes, the complication of hyperthyroidism aggravates it and increases the insulin requirement. Iodine acts very favorably on the tolerance of the diabetic patient, and thyroidectomy, which reduces the metabolic rate, acts favorably in such complicated cases. Hyperthyroidism, which causes rise in metabolism, is a very dangerous complication. Drugs that lower the metabolism in hyperthyroidism have a good effect on the tolerance of the patient with diabetes. The only exception to this rule is exercise, which seems to have the reverse effect. These observations deserve especial attention, the most significant thing being the influence of iodine in diabetes. This drug improves tolerance by lowering the metabolic rate, and when it does not lower the metabolic rate it has no influence. Therefore the body requires a given quantum of glucose, but it requires more insulin when the cell is stimulated by hyperthyroidism, which causes it to convert energy at a more rapid rate. The patient with no diabetes has more than enough insulin to meet excessive demands, but the patient with diabetes has not enough insulin for excess demands.

DISCUSSION

Dr. Henry A. Christian, Boston: The explanation given by Dr. Wilder is probably correct. A hyperthyroid condition overdrives the circulation, and if we carry out therapeusis for circulatory disease we undertake to give complete rest. Perhaps the ideal rest is in the condition of hypothyroidism, so that if we reduce thyroid efficiency we increase the potential efficiency of the circulation. If the patient has myxedema and also organic circulatory disturbance, we are confronted with a problem of curing the myxedema without harming the circulation. We sometimes have the problem of myxedema with anemia, combined with a myocardial lesion, which seems to be the effect of the myxedema. It is necessary to improve the anemia by improving the myocardial condition by giving thyroid, but we are limited by the response in the already injured heart muscle. That relation between circulatory disturbance and thyroidism parallels closely diabetes with hyperthyroidism or hypothyroidism.

Dr. Elliott P. Joslin, Boston: When a diabetic patient has symptoms of hyperthyroidism, one should relieve the patient of the cause of the symptoms. Diabetic patients with hyperthyroidism should be operated on. The greatest emergency is the danger of overfeeding. Injudicious feeding, fever or any other cause that increases metabolism, such as hyperthyroidism, must be guarded against.

Dr. W. M. Boothby, Rochester, Minn.: Another group of patients who are very important are those with diabetic coma, who do not respond to the usual dosage of insulin, and have no infection. Reticulated Red Cells.—An analysis of the red blood cells in forty-nine cases of pernicious anemia is presented by Dameshek. He regards the reticulate count of the red cells as a true index of bone marrow activity. Before and at the beginning of any remission or permanent rise in red count, the reticulate count surpasses 6 per cent; as the culmination of the rise is reached, it gradually falls to normal (from 0.5 to 1 per cent). With bone marrow aplasia, the reticulate count is extremely low, practically nil. There is no better index to prognosis in pernicious anemia than the count of the reticulated cells. Although these are frequently increased, and an elevation up to 5 per cent represents probably regeneration going on in the face of greater destruction—a sudden rise in count to more than 6 per cent presages a coming remission, overbalancing destructive forces. Very grave are the continued low counts that bespeak forthcoming death.

Dr. Robert Kelly Library

The relapse in pernicious anemia is closely related or at least extremely similar to aplastic anemia, which with its evident bone marrow failure, has an almost absent reticulate count. Platelet regeneration and aplasia are apparently closely related to red cell growth, for in purpura hemorrhagica the reticulate count goes up before recovery and remains low, with impending death from hemorrhages In the field of diagnosis, the marked reticulosis in congenital hemolytic anemia is a pathognomonic point differentiating that disease from all other anemias with large spleens.

Influence of Dihydroxyacetone on Blood Sugar and Glycosuria.—Thirty-four cases are reviewed by Mason He shows that, in patients with a normal carbohydrate tolerance, the ingestion of dihydroxyacetone in 25 or 50 Gm doses results in a very slight transitory rise in the blood sugar. When it is given in small interrupted doses, there is a progressive fall. In diabetes mellitus the increment increase in blood sugar is not as great after dihydroxyacetone as after a like dose of glucose. When it is introduced intravenously in a dose of 25 Gm, diabetic patients, with a fair carbohydrate tolerance, show very little rise in the blood sugar. Dihydroxyacetone, ingested in small but frequent doses in three cases of diabetes mellitus in short period experiments, could not be accounted for by the glucose excretion and the tissue retention. The results are suggestive that in certain cases of diabetes mellitus the ingested dihydroxyacetone is not quantitatively converted into glucose.

Classification of Pseudoleukemia.—Waugh divides the leukemias into three varieties· clinical, hematologic and histologic. Clinically, pseudoleukemia stands for a quite distinct symptom complex. The hematologic pseudoleukemias are characterized by a blood picture which simulates that of a leukemia. Pseudoleukemias in the histologic sense include, among others, the metaplasias and status lymphaticus.

Splenectomy for Purpura Hemorrhagica.—The case reported by Harris was one of essential thrombocytopenic purpura of severe degree, occurring in a girl, aged 11. Transfusion was of some palliative value, but splenectomy produced an immediate cure. The clinical picture and the result from splenectomy are in accord with previously reported cases.

Blood Regeneration.—The dietary factors which Eddy and Downs have found to favor production of hemoglobin and red blood corpuscles, arranged in the order of their importance, are cooked beef liver, lean beef and beef heart, spinach and beet tops, fruits and other green vegetables. Rigidly controlled experiments failed to show any beneficial effect on blood regeneration of arsenic or germanium dioxide, and iron was effective only if the iron reserve of the organism was exhausted. Favorable results have been obtained by the oral administration of dried powdered spleen and red bone marrow in the majority of cases of secondary anemia in which the combination has been tried. Experimental findings strongly suggest a trial of secretin in similar cases.

Potency of Digitalis and Strophanthus Tinctures.—The samples of tincture of digitalis assayed by Ward varied in strength from 30 to 150 per cent, or from a point 70 per cent below the standard of the U. S. Pharmacopeia, to a point 230 per cent above the same standard; that is, some samples are ten times as strong as others. This variation is between samples put out by two different manufacturers. But the samples of the same manufacturer vary; one sample has not been found as strong as another sample purchased elsewhere or at a different time. The variation in potency of tinctures of strophanthus ran parallel to that of digitalis. Some samples were 80 per cent below standard and others 430 per cent above standard. The variation between manufacturers' preparations was very marked, and the variation between samples of the same manufacturer was also marked.

Ephedrine in Bronchial Asthma.—The conclusions drawn by MacDermot from his experiences are that ephedrine produces well-marked antispasmodic effects in asthma, and that these are of longer duration than those produced by epinephrine in similar cases, and that repeated doses may be safely given over prolonged periods.

*Operation for Abductor Paralysis of Hip P. C. Colonna, New York. —p 177

Operation for Abductor Paralysis of Hip.—The operation proposed by Colonna is said to be of value in cases with paralysis of the hip if the quadriceps femoris muscle is active. It is proposed to take advantage of a portion of the quadriceps femoris muscle by detaching the long head, the rectus femoris, from its two origins and freeing this portion from its bed for a few inches; this long head is then brought through the fascia lata and is placed superficially to the tensor fascia lata, after which it is inserted into the crest of the ilium or fascia covering the paralyzed gluteus medius muscle.

*Self-Control and Inhibition in Suprarenal. W. Cramer.—p. 88.

Antigenic Properties of Diphtheria Toxin and Antitoxin.—With the use of the same diphtheria toxin and antitoxin, an overneutralized, a neutral and an underneutralized (toxic) mixture have been prepared by Hartley. The antigenic properties of the washed precipitates, which separated from these mixtures, have been investigated. The toxic and antigenic properties of these precipitates bear a close relationship to the nature of the mixture from which they are derived. The precipitate from the overneutralized mixture was atoxic, and its antigenic activity was small; the precipitate from the neutral mixture was also devoid of toxicity, but it was a good antigen; the precipitate from the toxic mixture was itself toxic when injected in relatively large doses, and it was also a remarkably active antigen. The precipitates contain less than 1 per cent of the total nitrogen present in the mixtures from which they separate. Some evidence has been obtained which suggests that the large amount of extraneous nitrogenous compounds which toxin-antitoxin mixtures contain interferes with the production of antitoxin. Antitoxin production follows the injection of very small amounts of those precipitates which separate from neutral or toxic mixtures.

Volumetric Measurement by Drops.—The effect of the rate of delivering drops on the weight of the drops is demonstrated by Fildes and Smart, and the relation of the external diameter of the dropping-tube to the weight of the drop is shown over the whole range in which drops of water can be delivered in air. Nomograms have been prepared to show at a glance the relationships between drop-weight, drop-rate and the size of the pipet.

Self-Control and Inhibition in Suprarenal.—Cramer asserts that the suprarenal possesses the power to control its functional activity in such a way as to prevent the gland from stimulating itself to complete exhaustion. The existence of such a mechanism is necessitated by the fact that the gland is stimulated to secretion by the sympathetic, and secretes as its specific hormone a substance—epinephrine—which itself specifically stimulates the sympathetic. It is shown that the injection of epinephrine and also prolonged feeding with thyroid produce characteristic changes in the suprarenal medulla, which effect a "self-control" of the gland. In addition, there is a mechanism which effects an "inhibition" of the functional activity of the gland. This mechanism is located in the cortex and manifests itself as a disappearance of the cortical lipoid. It can be most readily demonstrated by exposing an animal to conditions such as a hot environment, under which an activity of the gland would lead to the death of the animal by heatstroke. The bearing of these conceptions on the pathology of the suprarenal and thyroid is discussed.

Four Human Blood Groups: Agglutination Titers; Abnormal Donors. A. R. Jones and E. E. Glynn.—p. 203.

Abortus and Tubercle Bacilli in Cow's Milk.—Wilson and Nutt assert that about 5.7 per cent of single milks and 8.8 per cent of mixed milks are infected with *Brucella abortus.* Incidentally, 13 per cent of mixed milks have been found to contain the tubercle bacillus.

Histology of Thyroid and Parathyroids.—A reticle of endothelial cells is described by Williamson and Pearse in the thyroid and parathyroid bodies. Individual cells of this reticle appear, under certain circumstances, as large stellate granular cells. These stellate cells are compared to the Kupffer cells of the liver. The contents of the cytoplasm of the reticulo-endothelial cells vary with variations in the functional activity of the thyroid and parathyroid glands.

Oxygen Consumption of Muscle.—Harding states that the oxygen consumption of muscle wasted as the result of an arthritis is definitely increased above the normal, whereas that of muscles wasted as the result of disuse is unaltered.

Calcification in Rabbit's Brain.—An incrustation of nerve cells and a deposition of either globular or granular material have been observed by Da Fano and Perdrau in the brains of two rabbits which, owing presumably to partial immunity, had clinically recovered from an herpetic encephalitis. In addition, in one of them, the parasites of so-called spontaneous encephalitis had been found. Both incrustations and depositions were confined to brain areas in which a severe destructive infiltrative and reactive process had occurred. Their histologic aspect was suggestive of a process of calcareous degeneration, but microchemical reactions showed that they were due to a precipitation of iron salts on necrotic nerve cells and on a substance having in the specimens a coagulated appearance. These changes having occurred during the evolution of an inflammatory process, the supposition is that both the incrustating iron salts and the coagulable material had a hematogenous origin, and were presumably connected with the presence in the affected brain regions of an exudation possibly containing hemoglobin.

*Atrioventricular Bradycardia. D. Danielopolu and G. G. Proca.—p. 217.

Auriculoventricular Heart Rhythm.—The whole of this profusely illustrated issue is devoted to Danielopolu and Proca's research on the rhythm as long studied in two clinical cases. They explain the mechanism of the transient transformation of auriculoventricular bradycardia into flutter. They also describe the action on the heart rhythm of the vagus test, compression of the eyeball, digitalis, epinephrine, efforts, forced respiration and swallowing. There is reported a case of atrioventricular bradycardia with electrocardiograms revealing a ventricular complex between two auricular complexes. In another observation the atrioventricular rhythm coexisted with a partial auricular flutter. The technic is given for exploration of the auriculoventricular rhythm; its graphic character and forms, anatomic location of the contractions, and the mechanism of heart block in general.

Mediastinal Pleurisy in Children. J. Comby.—p. 220.

False Kernig Sign in Acute Anterior Poliomyelitis.—Morquio describes what he calls the pseudo-Kernig sign, observed in the painful form of anterior poliomyelitis, in South America. When the child is made to sit up, it protests with distress, on account of the pain, throwing its head back and stiffening the neck and spine. But if it is placed on the edge of the bed, the thighs gently flexed, the pain and rigidity disappear, and the child no longer resists. The rigidity in this case is more pronounced than in meningitis. There is no parallelism between the functional disturbance and the cell changes. The false Kernig sign does not seem to be connected with changes in the cerebrospinal fluid. The sign is absent in the meningitis form of anterior poliomyelitis. It may be of help in diagnosis of dubious cases, or in differentiation from meningeal conditions.

*Migration of a Projectile. De Saint-Avid and Léonard.—p. 532.
*Has the Appendix an Endocrine Function? Moutier and Fouché.—p. 532.

Action of Pituitary Extract on Diuresis.—Labbé, Violle and Azerad's research demonstrated that injections of pituitary extract, especially of the posterior lobe, seem to reduce the urine secretion in persons with normal water metabolism. The diuresis appeared unchanged if the injections were given before the night sleep. This is compared with Smith and Closky's results in rabbits. In these animals, oliguria from pituitary extract changed into polyuria under the influence of anesthesia. The decrease of urine secretion may be explained by the vasoconstrictor action in the kidney of the pituitary extract. It is partly inhibited under the general vasodilatation that occurs during sleep.

Migration of a Projectile.—De Saint-Avid and Léonard found in the right lung a scrap of projectile which had entered the left thigh six years before. The man was complaining of severe pain in the region of the right nipple, and bloody sputum. Roentgenograms showed a shadow in the right lung hilum, the size of a pea. Auscultation revealed fine, moist râles at the point of the scapula. The lesions of the lung seemed to be of a chronic character, the projectile having been carried to the lung in a short time.

Has the Appendix an Endocrine Function?—Moutier and Fouché observed notable obesity after appendectomy in five cases; disturbances of ovarian functioning in three; dysmenorrhea or amenorrhea, persisting for one to three years, with hyperthyroidism. In two instances removal of the appendix had apparently induced a syndrome of infantilism. Their conclusion is that the appendix seems to have a certain endocrine function. Its insufficiency may be gradually compensated in chronic cases. All their patients were operated on at the onset of appendicitis.

*"Dietotoxic Foods." G. Mouriquand.—p. 545.
*Treatment of Ovarian Insufficiency. A. Crainicianu.—p. 545.
Bacteriophage Treatment of Urinary Infections. A. Ravina.—p. 548.

"Dietotoxicity": Conditionally Toxic Elements in Foods.—In Mouriquand's experiments on guinea-pigs, about 2 cc. of cod liver oil was added to the food, consisting of maize, hay and lemon juice. No general or bone disturbances were noted. Then the hay was omitted; the animals then developed grave lesions of the bones with spontaneous fractures and hemorrhages. All these symptoms disappeared as soon as hay was given again, although the oil was still continued. Evidently cod liver oil may be a bone nutrient with a balanced diet; or it may induce dystrophic changes with an unbalanced diet. Substances nontoxic in themselves or with normal feeding seem to reveal a latent toxicity with an unbalanced diet. These "dietotoxic" substances may not induce typical phenomena of poisoning or anaphylaxis; but may possibly entail phenomena of autointoxication or idiosyncrasy.

Calcium in Treatment of Ovary Insufficiency.—Crainicianu found a reduced sympathetic and parasympathetic tonus in over 100 cases of congenital or acquired ovarian insufficiency. Calcium was administered to influence the tonus. Four or six daily doses of 1.5 Gm. of calcium lactate were given by the mouth for ten days; if necessary, repeated after a few days. The tonus of the involuntary nervous system rose to normal and all pathologic symptoms completely disappeared two or three weeks later. Large doses of the calcium did not induce digestive disturbances. It seems that accumulation of calcium may be necessary for restoration of the disturbed vagosympathetic balance from ovarian deficiency. The balance may be connected with the calcium ion concentration in the organism.

*The Viscosity of the Blood. O. Da-Riu.—p. 535.
Action of Sodium Cacodylate on the Blood. P. Bissiri.—p. 545.

Calcium Chloride in Treatment of Effusions.—Oriani analyzes eight cases of pleurisy with effusion and two of polyserositis in all but one of which calcium chloride proved promptly effectual. Diuresis was promoted and the effusion was resorbed. The effect was most rapid and intense when salt was omitted from the diet. The ages ranged from 15 to 49. From 15 Gm. a day, at first, the dose was pushed to

30 Gm in four or five days, and the effusion had generally disappeared by the sixth day

Influence of Morphine on Diuresis.—Porru warns not to forget that, in minute doses morphine and its derivatives stimulate secretion of urine, while doses above 0 0001 Gm per kilogram of weight progressively check diuresis

The Skin Reactions—Zuccola emphasizes that the promptness or retarded appearance of the positive response to the tuberculin skin test is an important element for estimation of the outcome of the test It is important also to compare the results of several tests at rather long intervals to estimate the trend up or down

The Viscosity of the Blood in Relation to Heart Functioning.—Da-Riu concludes from the data presented that increased viscosity of the blood after slight physical exertion testifies to weakening of the heart Squill reduces the diastolic pressure and also tends to lower an abnormally high systolic pressure It increases the viscosity at first, but later reduces it, and has proved useful in this line

Reflex Blood Pressure Changes During Operations—Schaefer recorded the blood pressure in 220 patients during operations on various regions and for various conditions In the greater number the blood pressure was uninfluenced It was increased in a few cases, in which the patient s general condition was good Lowered blood pressure, which is more dangerous, was observed frequently when the general condition was poor, and especially during operations on certain regions Operative injury or irritation of organs in the splanchnic region may cause a reflex loss of vascular tonus of this region, producing collapse Irritation of the carotid in goiter operations and of the sensory nerves easily leads by reflex action to lowered blood pressures Strong irritation is necessary to lower blood pressure Heightened blood pressure is caused by irritation of medium intensity When the vasoconstrictor system is already weakened by disease, an irritation otherwise slight acts as severe Reflexes affecting blood pressure may be excited from any part of the body and Schaefer believes that the operation itself is thus responsible for many cases of altered blood pressure heretofore ascribed to the narcotic Ether or chloroform will lower blood pressure in weak persons In strong persons ether has usually no effect on the blood pressure, chloroform lowers it moderately Local anesthesia raises blood pressure in the strong through its psychic effect

Experimental Studies in the Plastic Repair of the Bile Ducts—From fifty-three experiments on dogs, Muzeneek regards bridging the defect with a rubber drain, covered with suitable tissue flaps, as the most practical method of plastic repair of fresh injuries of the bile ducts where choledochoduodenostomy or hepaticoduodenostomy is impossible The drain assures the flow of bile and prevents stenosis of the newly formed passage It is necessary that the ends of the drain be firmly sutured to the duct walls, for if it slips out during the granulation process, obliteration of the passage results He found omentum and segments of veins the best covering The tissues soon degenerated into scar tissue, which, in shrinking, shortened the defect, drawing the duodenum toward the liver The inner surface of the tube of scar tissue became covered with epithelium Further studies must determine how long it is necessary for the rubber drain to remain in place, but these experiments have emphasized the desirability of its remaining as long as possible

Hydrocele and Workmen's Compensation—Scheele studied the evidence in 133 cases of alleged traumatic origin or aggravation of hydrocele Because of its mobility, force applied directly to the testicle must possess a certain suddenness if it is to cause injury Although the hydrocele itself may not form until two or three months have elapsed and external signs of injury have disappeared, the immediate subjective results of the injury are severe If these immediate results are lacking in the history, suspicion is cast on the traumatic origin The most frequent consequence of trauma to the testicle is hematoma outside the vaginalis, this may lead to hematoma within the vaginalis, which in turn may lead through irritation from hemorrhagic remains or traumatic periorchitis to hydrocele Hematoma within the vaginalis however is rare, except where hydrocele already exists Hydrocele caused by indirect force, such as strains in lifting, jumping backward or slipping when carrying a heavy burden, is rare, but possible When infection of the testicle or epididymis exists at the time of the accident, the question of traumatic origin of the hydrocele becomes more complicated, for hydrocele may develop in local infection without trauma; on the other hand, the trauma may be responsible for aggravation of the original condition, which might not otherwise have led to hydrocele. A large hydrocele is continually exposed to trauma. Injury may make the condition worse or introduce complications, but in considering the question from the compensation angle, the possibilities in the natural course of the trouble, such as hemorrhagic periorchitis and spontaneous rupture of the wall, must be remembered.

Arteriovenous Intercommunication.—Eppinger, Kisch and Schwarz connected the abdominal aorta and vena cava in cats by a tube which could be closed. After opening the connection, the arterial pressure dropped by 40 mm. of mercury; the pulse increased by 14 beats per minute and the volume of the single beat increased by 0.96 cc. in one of their experiments. With this short-circuiting of the blood stream, in spite of the lowered peripheral resistance and arterial pressure, the heart has to perform more work because of the increased output.

Invisible and Uncultivable Bacilli.—Friedberger points out that the isolation of germs rarely succeeds in the beginning of epidemics. The findings are usually negative in the first cases of cholera and influenza. He explains this by the possibility that the real infection is caused by an uncultivable and filtrable form of the germ. The known visible forms develop later and are less virulent. Three years ago he was able to change typhoid bacilli into such a form which produced infection in guinea-pigs and which was far more potent in immunization than heated cultures. Similar experiments have been reported recently with tuberculosis bacilli. If the filtrability of the tuberculous virus had been detected previously to Koch's discovery, the acknowledgment of the visible forms as causative agents would have been delayed, just as has been the case with scarlet fever streptococci. He finds increasing evidence as to the etiologic significance of the Weil-Felix bacillus for typhus fever. He points to the epidemiologic significance of these data, and sees a true nucleus in Pettenkofer's theory of the necessity of some sort of ripening of the germs before they become infectious.

Inhibiting Culture Bouillon.—Dresel treated broth with 10 per cent of its weight of charcoal. The medium became acid and the growth of pathogenic germs was strongly inhibited. He regards this change of reaction as a valuable addition to the absorbing power of the charcoal.

Ions in Growing Bones.—Stoye describes a method for histochemical demonstration of soluble phosphates in growing bones. They are localized in the form of a narrow transverse band in the zone of cartilaginous cells.

Epizootics in Mice.—Okamoto observed among animals several instances of activation of a latent infection by accidental agents. Such was the case with certain mice infected with sublethal doses of mouse-typhoid. Injection of the homologous bacteriophage was the provoking factor. Injection of organ extracts from rabbits awakened a latent paratyphoid B infection in guinea-pigs. Some female guinea-pigs died after labor under symptoms of grave diplococcus septicemia. The male animals injected with the germs seemed resistant until a sudden frost set in. The next day five out of eight males that had been infected previously developed the same symptoms as the females.

Monatsschrift für Kinderheilkunde, Leipzig

32: 1-96 (April) 1926

*Digitalis. B. Samet and O. Tezner.—p. 1.
Puberty Metabolism. O. Göttche.—p. 22.
Ferments in Infant's Stomach. K. Waltner.—p. 37.
*Concentrated Buttermilk. H. Weil.—p. 40.

Digitalis.—Samet and Tezner tested the action of digitalis on healthy and sick children without insufficiency of the heart. Healthy children are as a rule comparatively resistant. In some of the pneumonia patients smaller doses produced arrhythmia. They do not attempt to decide whether its use is beneficial in pneumonia or not, but emphasize the necessity for continuous control, if it is administered.

Concentrated Buttermilk.—Weil reports good results with a concentrated food consisting of buttermilk with addition of 2 per cent flour and 13 per cent sugar. It is advisable for infants who have little appetite or drink badly, and especially with intolerance of fat, nervous vomiting or pylorospasm. The mixture contains about 100 calories per hundred grams. Consequently 100 Gm. per kilogram of body weight is sufficient food for a healthy infant.

Zeitschrift für Tuberkulose, Leipzig

45: 1-94 (April) 1926

*Primary Infiltration. F. Redeker.—p. 1.
Serial Sedimentation Tests in Diagnosis of Tuberculosis. Büchler and Nobel.—p. 7.
Tuberculin Sensitiveness and Action. H. Selter.—p. 11..
*Tuberculosis in Schools. K. A. Worringen.—p. 27.
"Myopia and Tuberculosis." G. Hirsch.—p. 32.
*"Wassermann's Tuberculosis Antigen." M. Pinner.—p. 34.
"Paralysis of Diaphragm." Hauke.—p. 38.

Primary Infiltration.—Redeker describes the clinical and especially the roentgenologic aspects of primary tuberculous lesions of lungs. A perifocal inflammation is the rule. It spreads toward the hilum, but it is most pronounced at both ends ("bipolar").

Tuberculosis in Schools.—Worringen concludes that school predisposes to the infection by lowering the resisting powers of the children. Four hours a day should be the maximum for elementary schools, and five hours for the upper grades, and no home work. Daily gymnastics are as essential as brushing the teeth and washing.

"Wassermann's Tuberculosis Antigen."—Pinner emphasizes that nearly all the active substances of the Wassermann tuberculosis antigen are soluble in alcohol. Divergent opinions of other authors are due only to the variations in the antigen and to the inaccurate methods they used.

Svenska Läkaresällskapets Handlingar, Stockholm

51: 207-237 (Dec. 31) 1925

*Treatment of Hemophilia. H. v. Samson-Himmelstjerna.—p. 207.
The Filament Galvanometer and the Measurement of the Heart's Action Current. W. Einthoven.—p. 213.
Actinomycosis; Two Cases of Foreign Body in Floor of Mouth. S. Norlén.—p. 227.

Nature of Hemophilia and Causal Treatment.—The treatment proposed is based on the familiar fact that hemophilia skips the female link in its transmission. It seems logical, therefore, to utilize in treatment the sex hormone that distinguishes the female. There seem to be waves of more or less pronounced preparedness for hemorrhages, explaining the periodicity of the tendency to bleed. Instances are known in which a change to a tropical or mountain climate has arrested this tendency. The influence of sunlight may explain this; the skin of certain bleeders seems to be abnormally delicate. Injection of blood probably owes its efficacy to protein shock; this may be the explanation of the beneficial effect of roentgen irradiation of the spleen, or injection of own blood. It might be possible to realize a shock treatment by way of the mouth. Everything points to the assumption that hemophilia is due to the occasional or periodic formation of a substance which damages the vessels. Ovarian extract (from cows), heliotherapy and shock treatment form a threefold mode of attacking hemophilia. There does not seem to be any danger from this artificial hermaphroditization with ovarian extract in males. No attempts to treat hemophiliacs on this basis have been tried, but it is advocated as theoretically rational.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE 1926

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in the United States and to Fellows of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No foreign journals are available prior to 1921, nor domestic journals prior to 1923. Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in The Journal. In the Current Medical Literature Department only the articles which have been abstracted are indexed

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "Ml," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics, 'ab," abstract; the star (*) indicates an original article in The Journal

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "B," "D" and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2058.

MEDICINE: ITS ACCOMPLISHMENTS AND ITS NEEDS*

JABEZ N. JACKSON, M.D.
KANSAS CITY, MO.

It is a great privilege to have lived in the present generation. Within its span more has been added to the sum of human knowledge than in any previous period of the world's history. The Golden Age it has been called—the Age of Science. Discovery after discovery has followed in such rapid sequence that the mind of ordinary man is awed with amazement. Fundamental principles of science, slowly comprehended through long periods of time past, have suddenly found practical application beyond even the vision of the dreamer. Through them man has been given mastery in a measure over land and sea and sky. The application of power to motion has revolutionized transportation and conquered space. By wire, by cable, by radio, through the air practically instantaneous communication around the world has been made possible. News and knowledge are thus promptly interchanged and the advances of one become the heritage of all. Machine power has lifted much of the burden from the human back and multiplied infinitely the possibilities of production. Cooperation has replaced segregation. Progress has been the watchword.

In the fields of medicine the workings of science have been none the less remarkable, though less obvious to the general eye. When the microscope first enabled us to comprehend the fundamental cellular structure of the body, the key to the ultimate interpretation of life was put in our hands. When Pasteur discovered the existence of other cellular organisms capable of attack on human cells, he gave to our science its first knowledge of the essential cause and nature of much of disease, and the new science of bacteriology was born. Through it pathology found a new interpretation and became a vital study. The culture tube and the reagent brought chemistry into the field, and through the three the laboratory became the center of medical investigation.

Brief though the span since the birth of these sciences, their contributions to human welfare have been numerous and of value inestimable. The knowledge of how to prevent many diseases has alone saved to the world countless lives and immeasurable expense. Cholera, which once with its death scythe stalked through nations, has become now but a name. Yellow fever, which almost annually gleaned its thousands of human lives and paralyzed commercial activity, has been driven to the far recesses of Africa, where the few cases reported in the past year evidence its dying gasps. The sanitary control of malaria and other infectious fevers made effective by Gorgas built the Panama Canal and rerouted the commerce of the world. Can one find figures in dollars and cents to estimate the commercial value alone of such contributions of preventive medicine? And these are only a few illustrations from this field.

Can one measure the numbers and the values of the lives of the many youngsters snatched from the jaws of diphtheria by the use of antitoxin, to say nothing of the anguish of apprehension and grief lifted from the hearts of parents? Typhoid alone forty years ago kept medical men supplied with a lucrative annual income, and its ravages in time of war frequently accounted for more lives than did bullets. Today through modern sanitation and with preventive inoculations, its existence has become a disgrace to the community and in an army almost a crime.

May these illustrations, few though they be, stand as a test to the efficiency of the "Great Medical Trust"—the only trust that ever existed to save billions of dollars and millions of lives and countless sorrow to mankind at the expense of its own sources of income.

CONTRIBUTIONS OF MEDICAL AND SURGICAL SCIENCE

The curative contributions of medical and surgical science have been no less notable, though obviously less noted. No one can estimate how many annually paid the toll of death in days gone by to what we may here call, in general, surgical diseases. With the almost inevitable infection and ofttimes death from wounds and surgical efforts, much of the body remained terra incognita until the postmortem table was reached. The immortal work begun by Lister in carrying the observations of Pasteur into the surgical field provided a revolution more significant than a revolution of arms—the one bringing peace and life, the other pain and death. The impunity with which the physical body could now be invaded enabled the bold surgeon to explore hidden disease and to bring to light the knowledge of their beginnings at a time when they might be amenable to cure; and from these early explorations an interpretation of hitherto unknown signs.

It seems almost strange in this day to recount that it was only in the eighties of 1800 that appendicitis was recognized as a definite entity and its sequences understood. Even as late as 1893 I heard a supposedly learned man say, "I have practiced medicine forty years and have never seen a case of appendicitis." And
